Wide Compact Binaries?

- Only close compact binaries known so far!
- Are there neutron star or black hole companions to M-dwarfs with orbital periods of several years?
- What could be the formation process for such systems?
 - Can the components evolve together, i.e. can the M-dwarf/the system survive the SN explosion of the massive component
 - Are such binaries a result of capture processes

Data set

- SDSS Stripe 82 catalogue by Bramich et al. 2008
→ 1998-2005; area: $\sim 250 \text{deg}^2$
- $20^{\text{h}} < \text{RA} < 4^{\text{h}}$, $-1.25^{\circ} < \text{DEC} < 1.25$
- 4 million stars and galaxies, repeatedly measured
- Providing photometric & astrometric measurements
- Mean positional uncertainty for stars: 35 mas
- For some objects spectra are available from the SDSS online database

Proper motions uncertainties provided by Bramich et al. (2008) catalogue are model errors \rightarrow systematic features

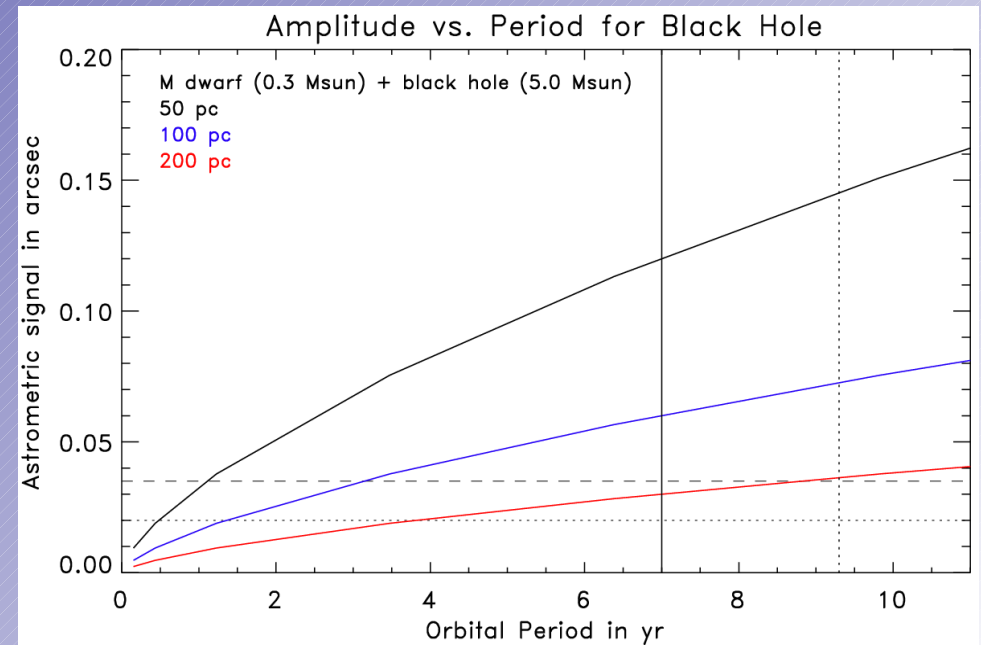

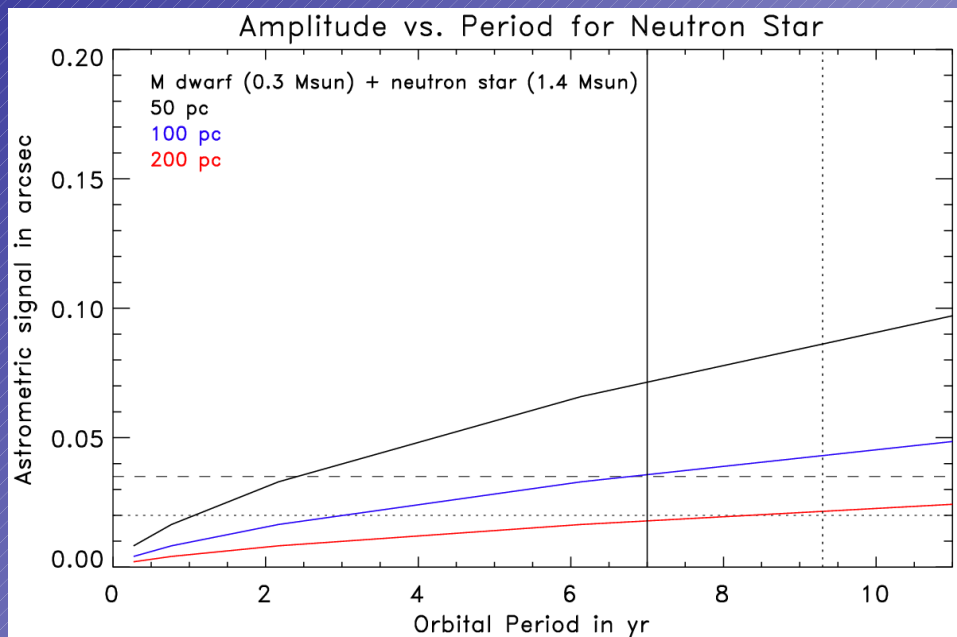

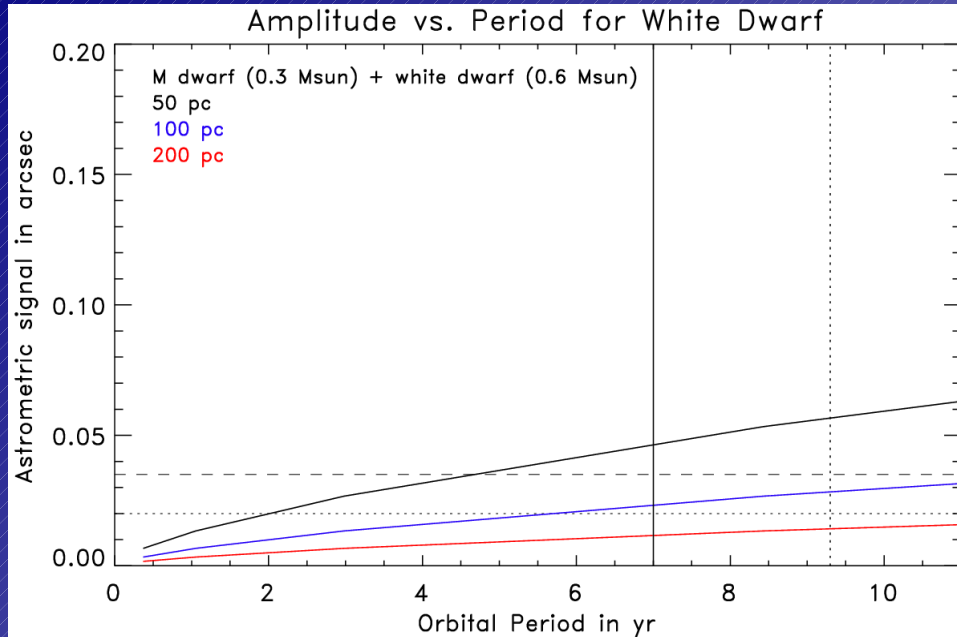

Obtain real proper motion uncertainties \rightarrow normalise with listed χ^2 values

General selection criteria

- For saturated or too faint objects proper motion uncertainty systematically larger → magnitude cut
- First sample only contains well measured stars, i.e. objects not showing outliers in motion curve
- Aim to find neutron stars or black holes to low-mass stars → light dominated by low-mass component → only consider apparently isolated stars
- Astrometric signal should exceed the positional uncertainties → nearby objects

We need nearby objects!
Preferably within 100pc
→ Proper motion $> 50\text{mas/yr}$

Binaries with larger mass ratio
show larger astrometric signal
→ the most interesting ones

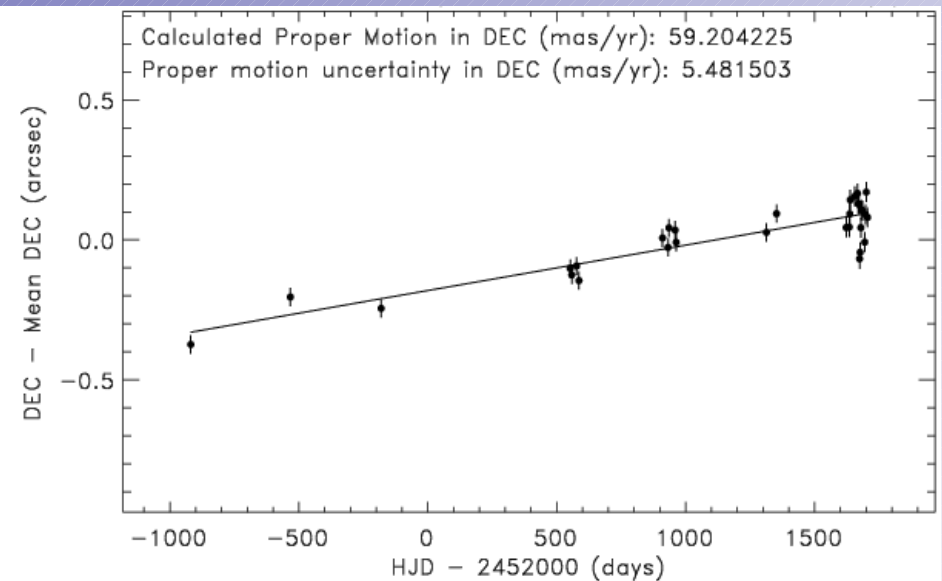

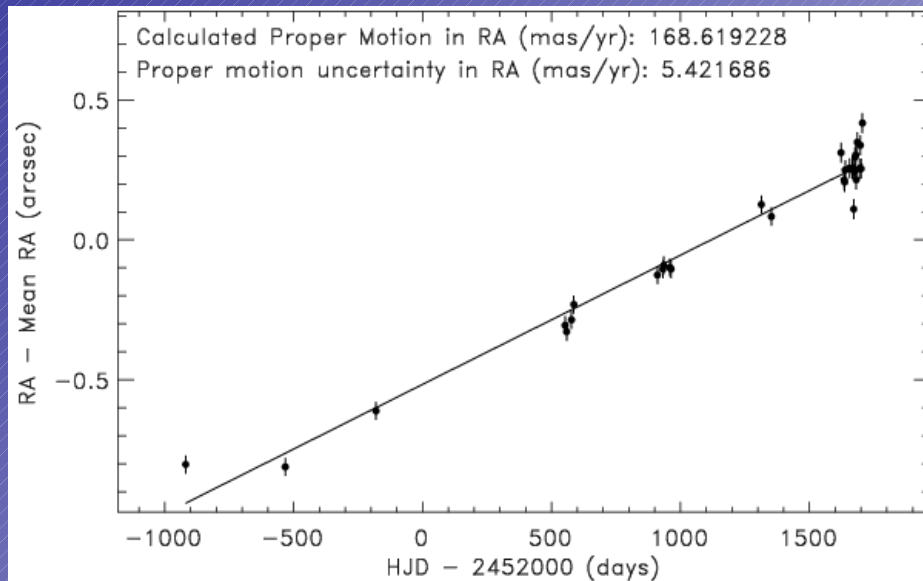

Two approaches to identify

- 1) Companion increases proper motion uncertainty ($\Delta\mu$) and the standard deviation of the positional residuals (σ_{Res}^2) \rightarrow comparison to values of similar objects (No. of Epochs ± 5 , r-mag ± 0.5)
 - 2) Binaries are periodic systems \rightarrow Lomb-Scargle periodograms and sine curve-fitting in each coordinate \rightarrow period equal in both coordinates
- \rightarrow Do both approaches lead to the same result?

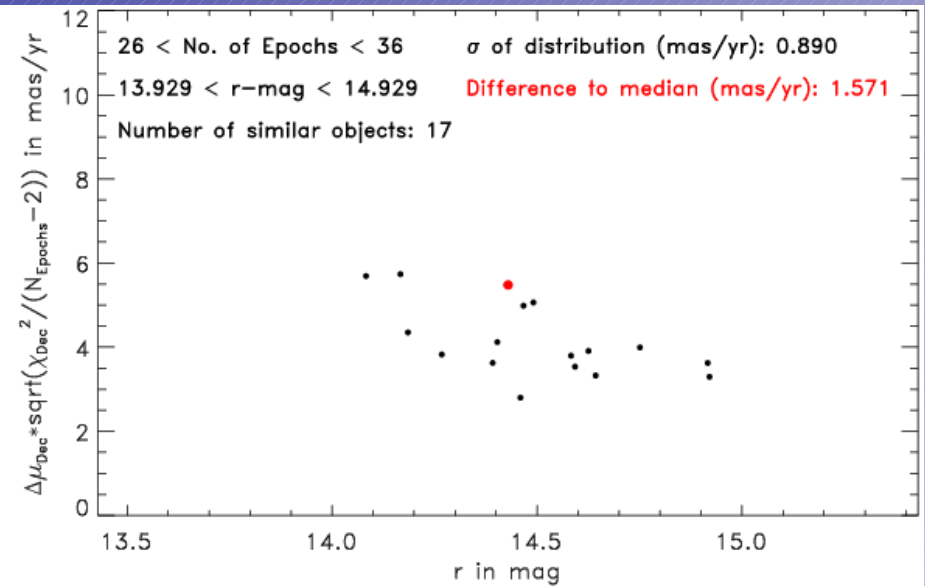

First approach: SDSS J2341-0114

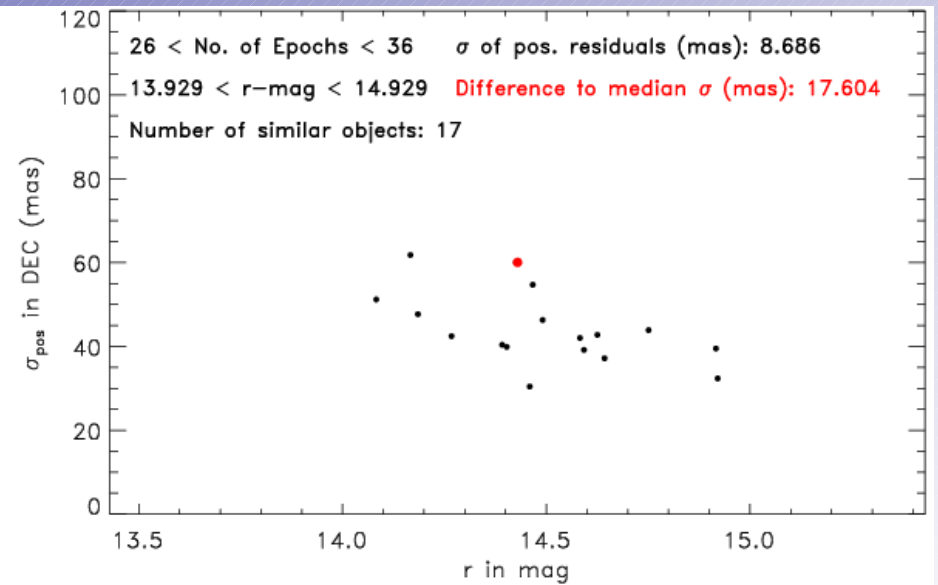

Spectral type: M2 dwarf
Distance: ~80 pc
 μ_{total} : 179 mas/yr
i mag: 13.4 mag
 M_i mag: 8.9 mag

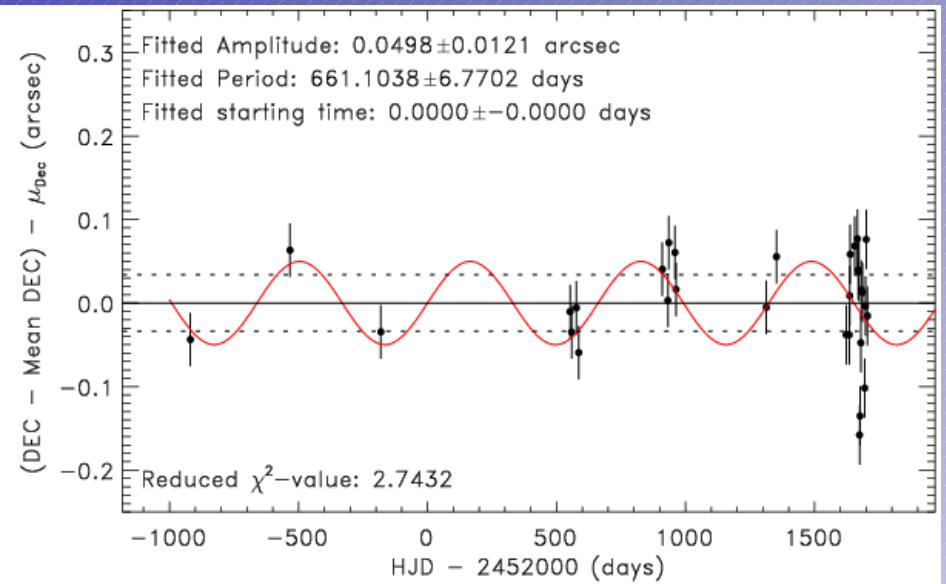

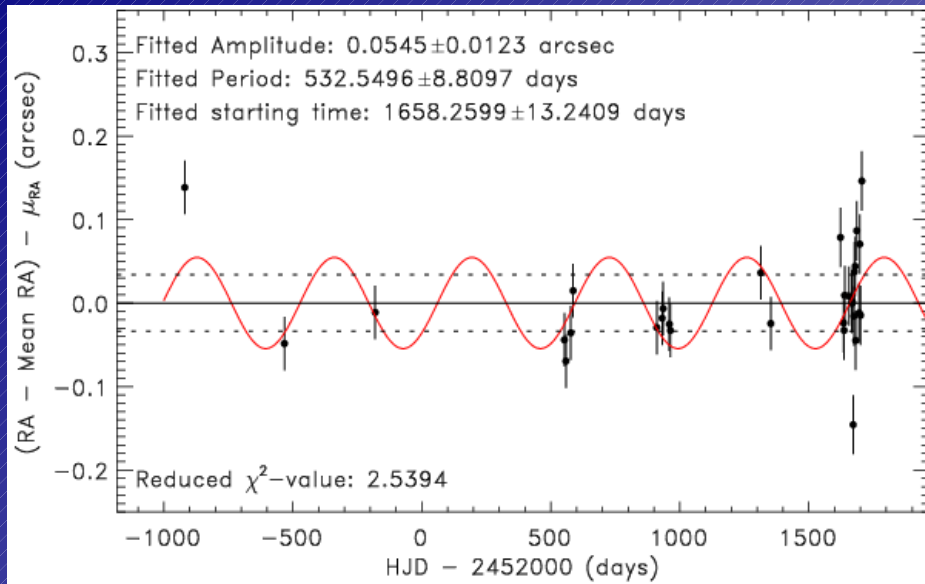

Proper motion uncertainty vs. r magnitude

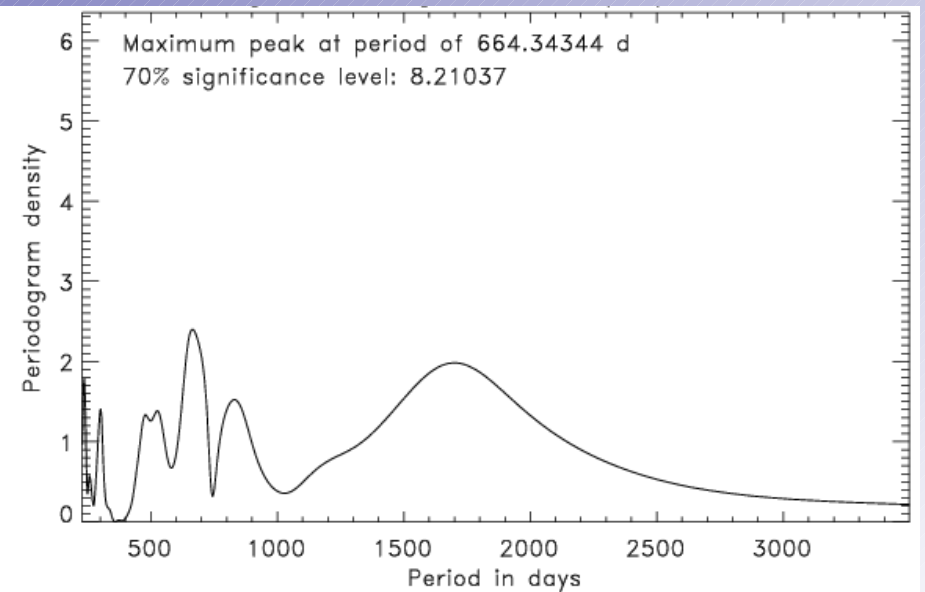

Standard deviation of positional residuals vs. r magnitude

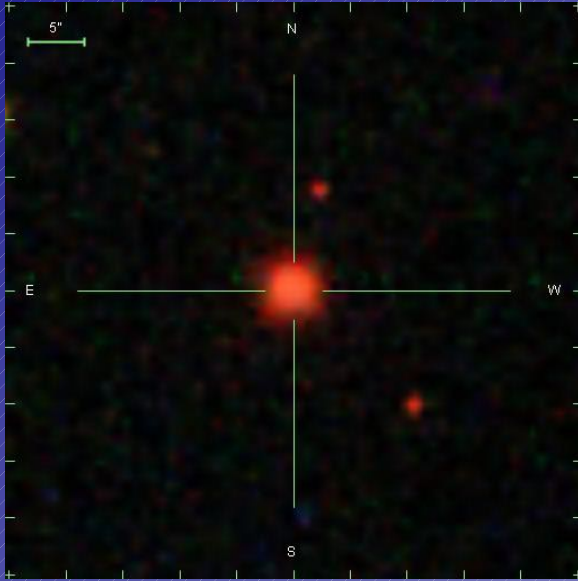

Sine-curve fitting in both coordinates

Lomb-Scargle periodogram in both coordinates

Second approach: SDSS J2325-0026

Spectral type: M4 dwarf

Distance: ~80 pc

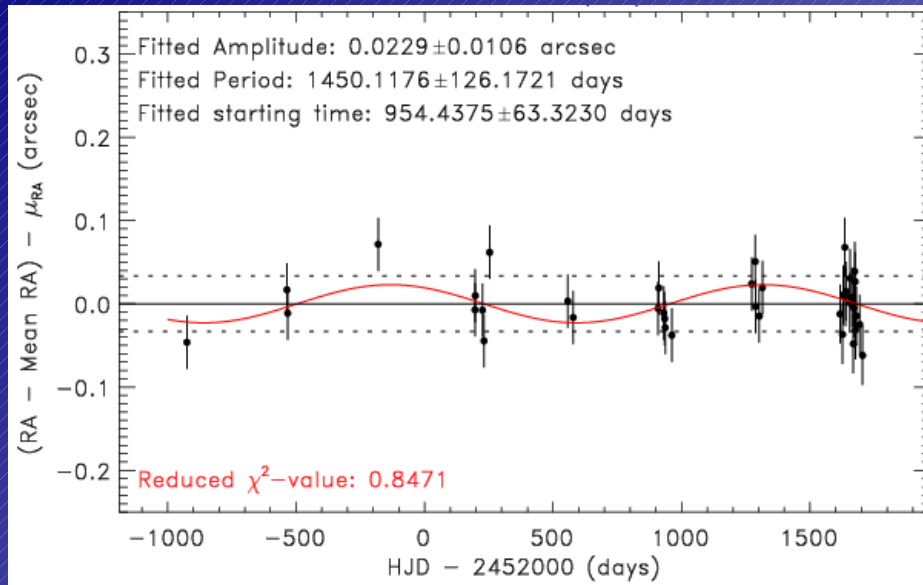

μ_{total} : 124 mas/yr

i mag: 15.5 mag

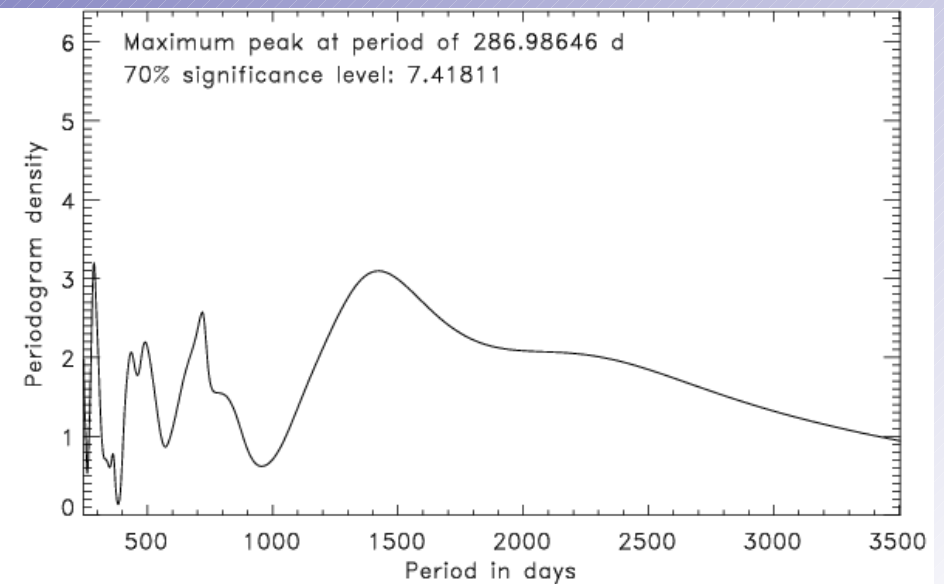

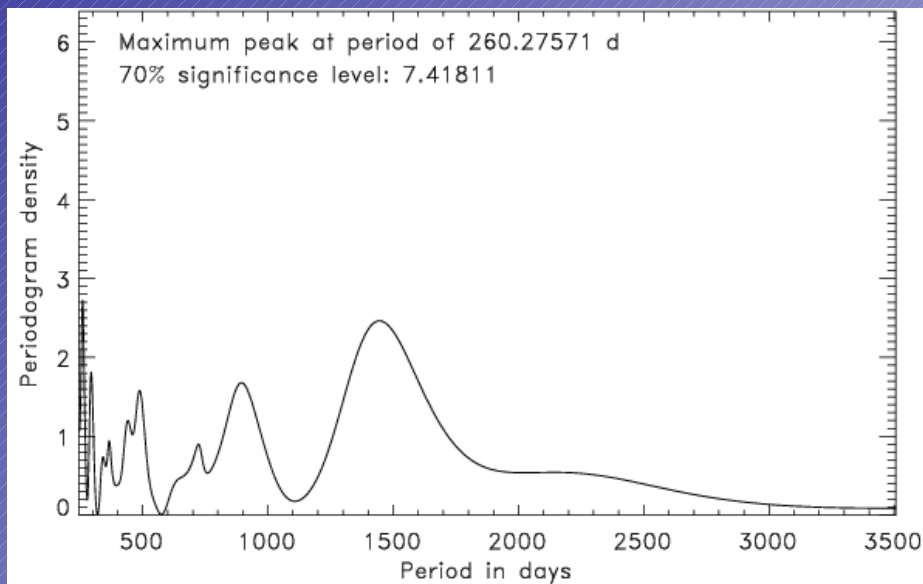

M_i mag: 10.8 mag

Sine-curve fitting in both coordinates

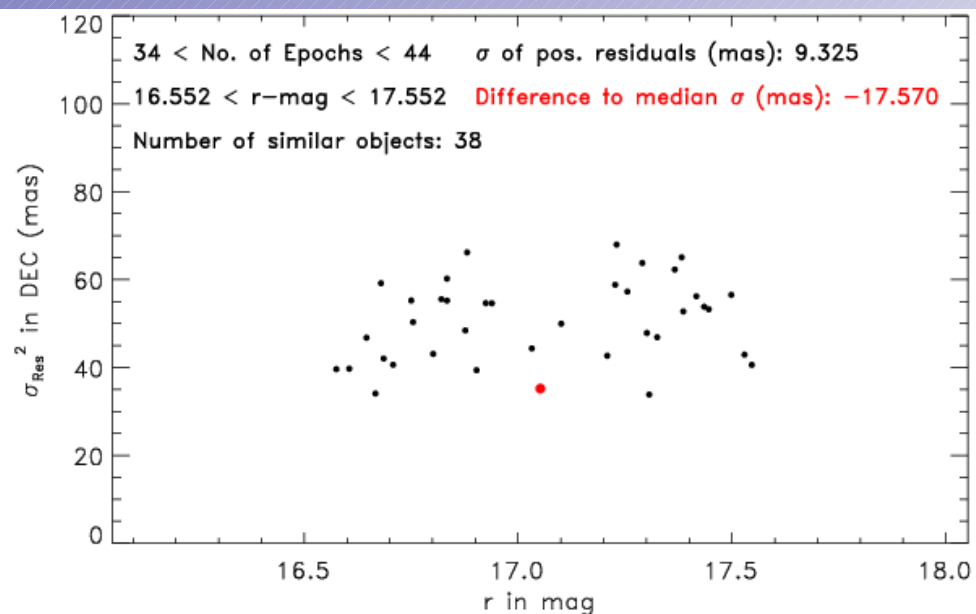

Lomb-Scargle periodogram in both coordinates

Proper motion uncertainty vs. r magnitude

Standard deviation of positional residuals vs. r magnitude

Open questions and future work

- Why do candidates show either good sine fit or are outliers in $\Delta\mu$ and σ_{Res}^2 ?
- Are the determined periods really significant?
- Resulting periods are different from sine-fit and lomb-scargle periodogram! Why?
- Orbit fit for best candidates
- Expanding data with online catalogue
- Own observations to confirm candidates

Thank you!
