

# Multiplicity in the early phases of stellar evolution

Gaspard Duchêne

UC Berkeley - IPAG (Grenoble)

**Berkeley**  
UNIVERSITY OF CALIFORNIA

# Stellar multiplicity

- Stellar multiplicity is
  - ▶ an ubiquitous feature of stellar populations
  - ▶ a product of the star formation process(es)
  - ▶ not a *fossil record*, however, because of (violent) stellar dynamics → see **R. Parker's talk**
- ***Need to probe the early phases of stellar evolution: PMS and protostars***

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# Outline

- Multiplicity to probe of core fragmentation
- Pre-Main Sequence multiplicity
- Protostellar multiplicity...
  - ▶ ... among Class I sources
  - ▶ ... among Class 0 sources
- Summary

# Stellar multiplicity

- Very broad range of separations on the MS
  - ▶ presumably not a single physical process

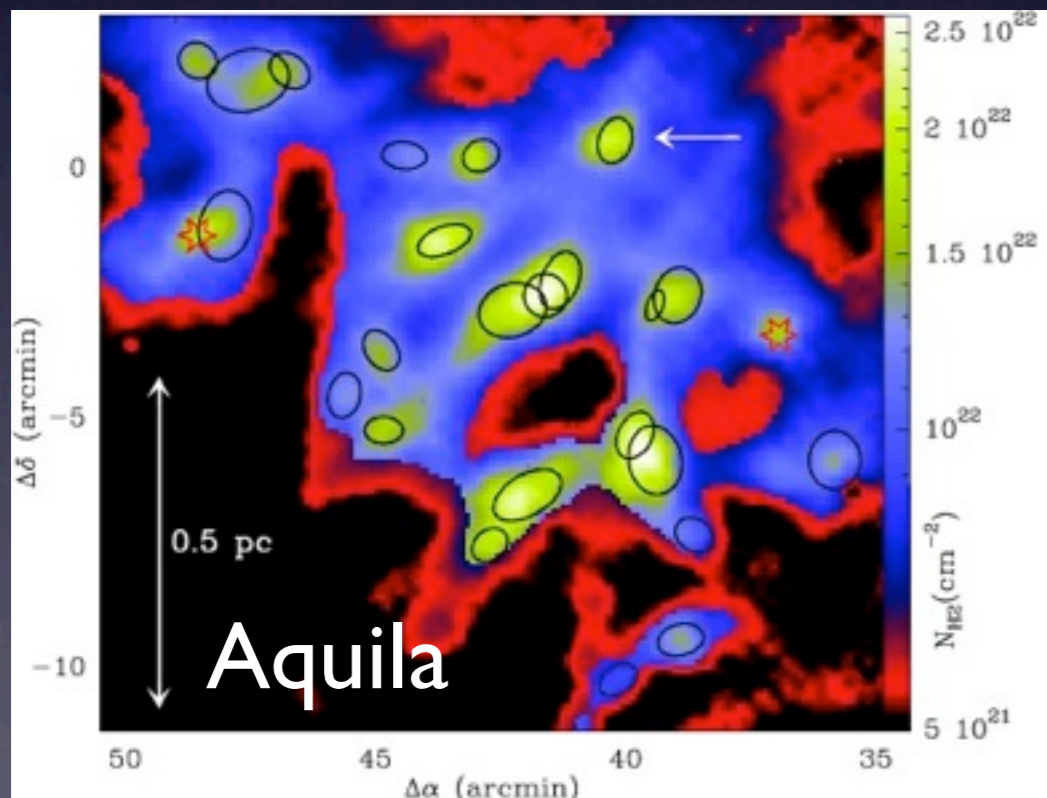

*Raghavan et al. (2010)*

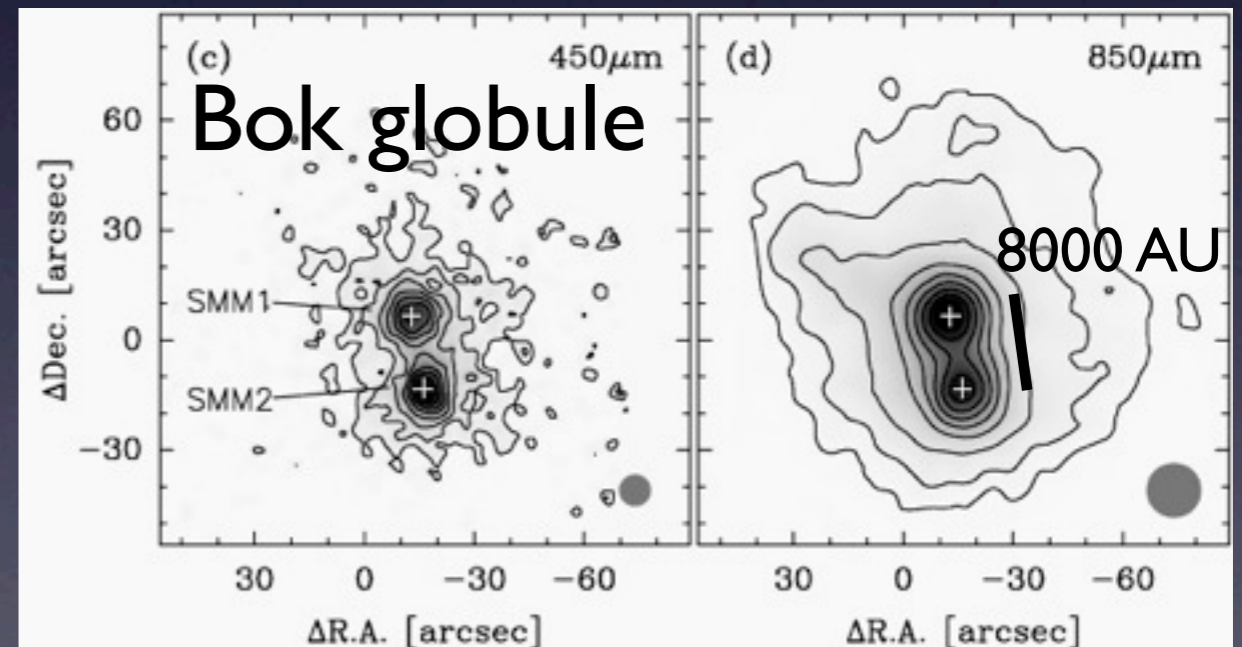

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# Stellar multiplicity

- Very broad range of separations on the MS
  - ▶ presumably not a single physical process
- “Typical” core size  $\sim 5000$  AU

Könyves et al. (2010)

Launhardt et al. (2010)

# Stellar multiplicity

- Most wide systems probably form from two separate, nearby, prestellar cores or much later during cluster dissolution

*Raghavan et al. (2010)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# Stellar multiplicity

- “Spectroscopic” binaries form through subsequent (disk) fragmentation *and* dynamical interactions

*Raghavan et al. (2010)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# Stellar multiplicity

- *Separation range  $\sim 50\text{-}5000\text{ AU}$  is the domain of core fragmentation*

▶ But may not be a pristine population!

*Raghavan et al. (2010)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# VLMS/BD multiplicity

- Not nearly as frequent as solar-type stars
  - ▶ Binary fraction  $\sim 20\text{-}35\%$

*Raghavan et al. (2010)*

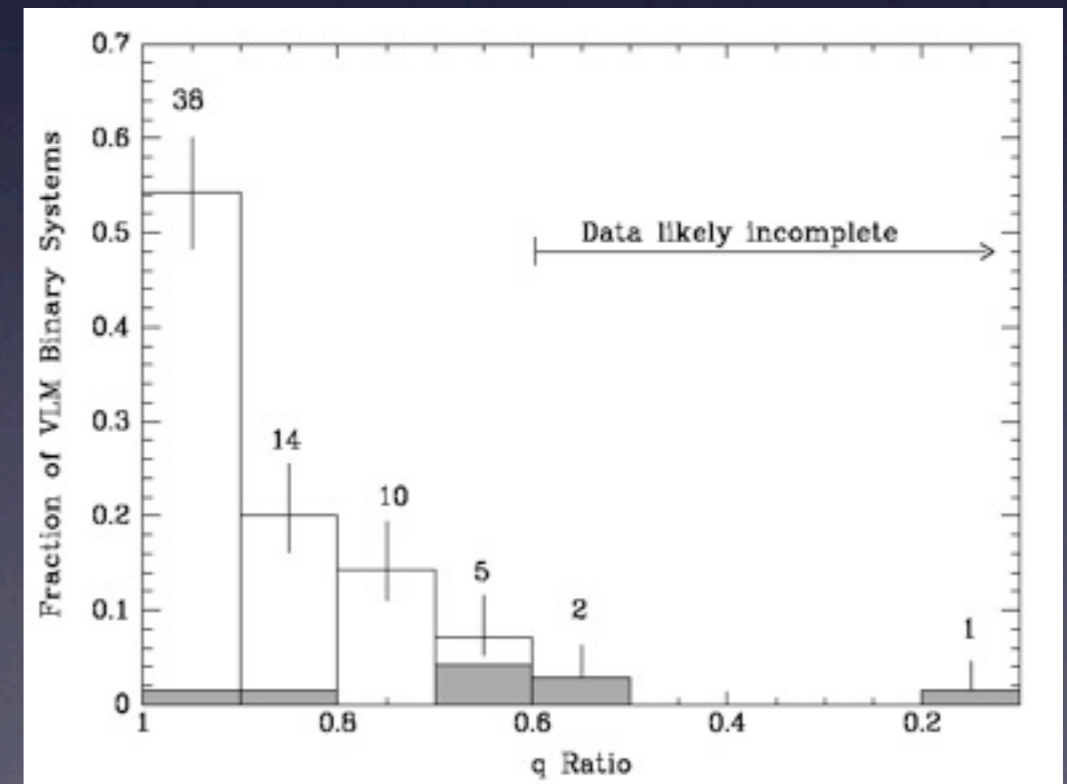

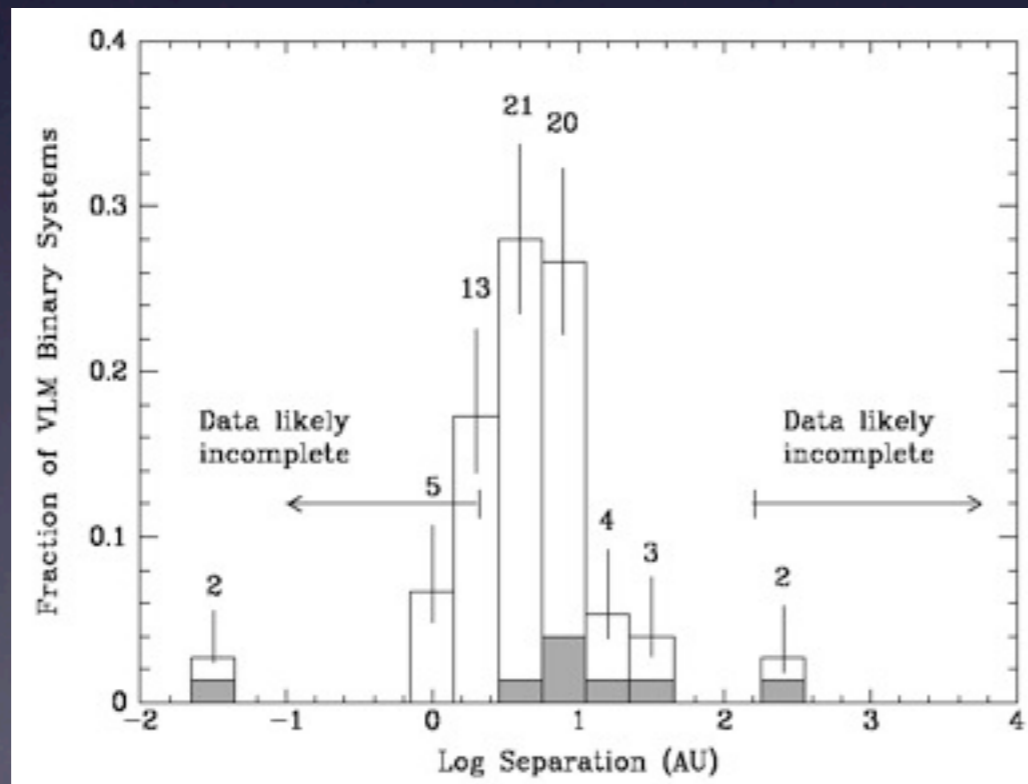

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# VLMS/BD multiplicity

- Not nearly as frequent as solar-type stars
- *Mostly* limited to very tight and equal-mass systems

Burgasser et al. (2007)

The formation of VLMSs and BDs - Garching - Oct 12 2011

# VLMS/BD multiplicity

- Not nearly as frequent as solar-type stars
- *Mostly* limited to very tight and equal-mass systems
- see Joergens', Dupuy's, Brandner's talks
- Are these properties related to the formation of these systems or driven by dynamical interactions? Test in the earlier phases...

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# VLMS/BD as companions

- VLMS/BD are quite rare at all separations around solar-type stars (“BD desert”)

*Metchev & Hillenbrand (2009)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# VLMS/BD as companions

- VLMS/BD are quite rare at all separations around solar-type stars (“BD desert”)
- For “wide” system, this is probably telling us about post-fragmentation accretion
  - ▶ or are they disrupted during dynamical interactions?

# PMS multiplicity

- Establishing statistical multiplicity properties in PMS phases faces several critical issues
  - ▶  $D > 100$  pc (subarcsecond resolution needed)
  - ▶ masses are (sometimes) difficult to estimate
  - ▶ incompleteness when envelopes are present
- ***The issues are getting worse as one goes further back in time!***

# T Tauri stars multiplicity

- Best-studied regions: Tau-Aur, Cha, Ori, Oph, Up Sco
  - ▶ Multiplicity is generally high
  - ▶  $CSF_{\text{Tau-Aur}} \sim 100\%$
  - ▶ fraction of single stars  $\sim 25\text{-}30\%$

Leinert et al. (1993)

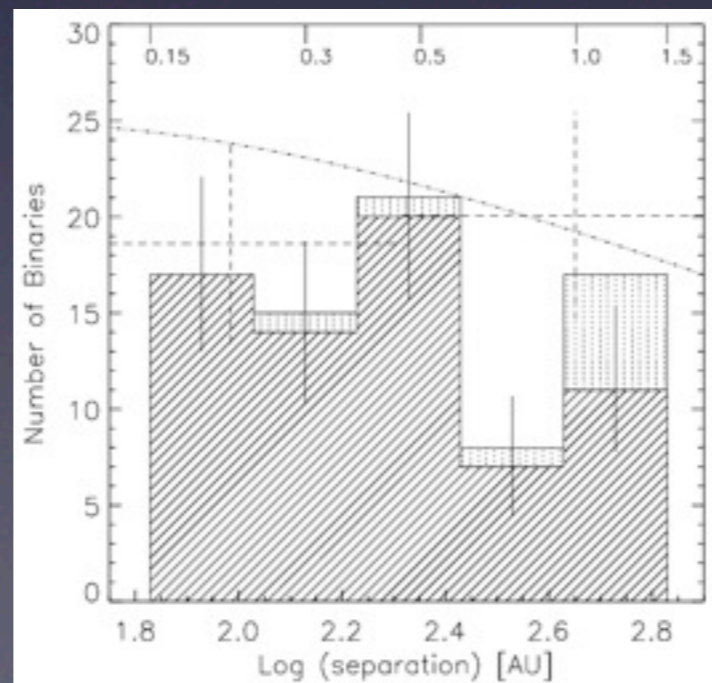

The formation of VLMSs and BDs - Garching - C

# T Tauri stars multiplicity

- Possibly environment-dependent: clusters vs. loose associations
  - ▶ No system wider than 1000 AU in the ONC (Sclally et al. 1999)
  - ▶ Much lower CSF in clusters

*Reipurth et al. (2007)*

*The formation of*

*Leinert et al. (1993)*

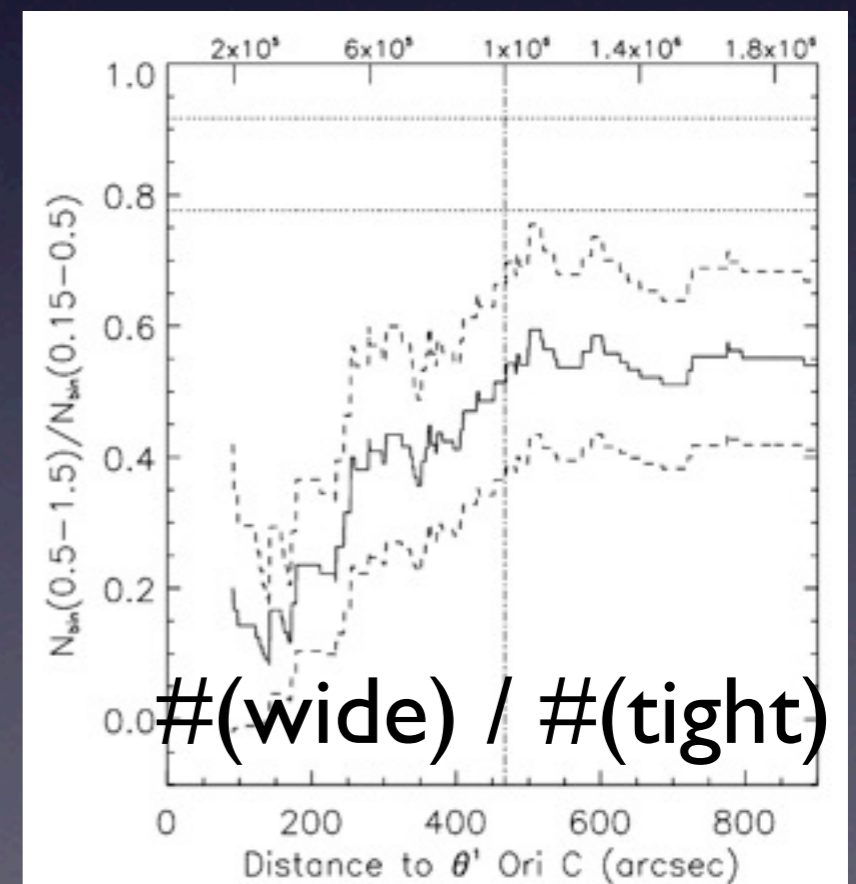

# T Tauri stars multiplicity

- Possibly environment-dependent: clusters vs. loose associations
  - ▶ No system wider than 1000 AU in the ONC (Sclally et al. 1999)
  - ▶ Much lower CSF in clusters
  - ▶ Evidence for binary disruption?
  - ▶ Or is it an intrinsic difference?

*Reipurth et al. (2007)*

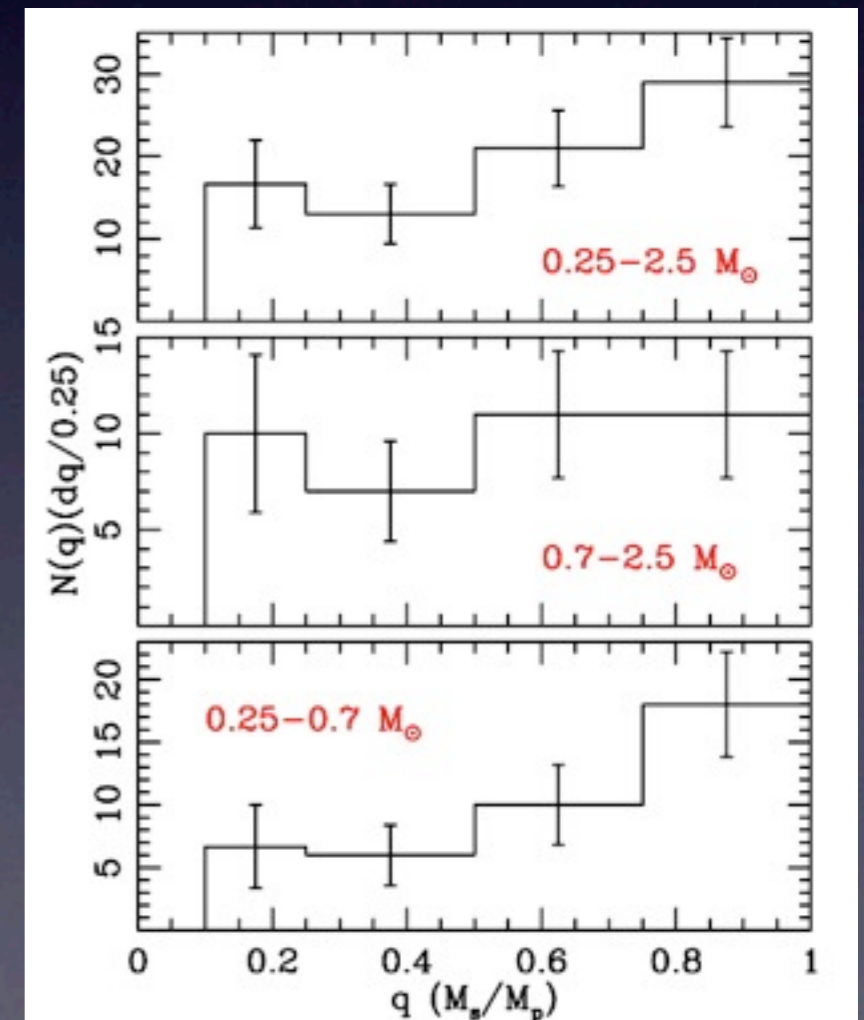

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# T Tauri stars multiplicity

- The mass ratio distribution is roughly flat for solar-type, *not* following the IMF
  - ▶ similar to the MS distributions

*Kraus et al. (2011)*

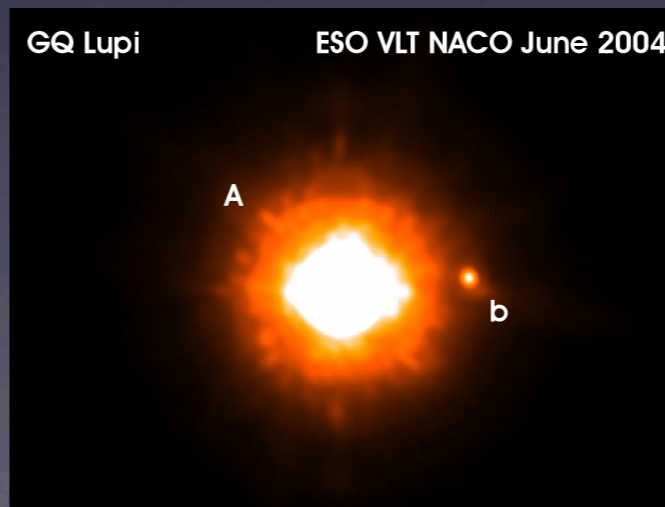

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# T Tauri stars multiplicity

- The mass ratio distribution is roughly flat for solar-type, *not* following the IMF
  - ▶ similar to the MS distributions
  - ▶ BD companions are less rare than among Main Sequence stars but not frequent either

*Chauvin et al. (2005)*

*Neuhauser et al. (2005)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

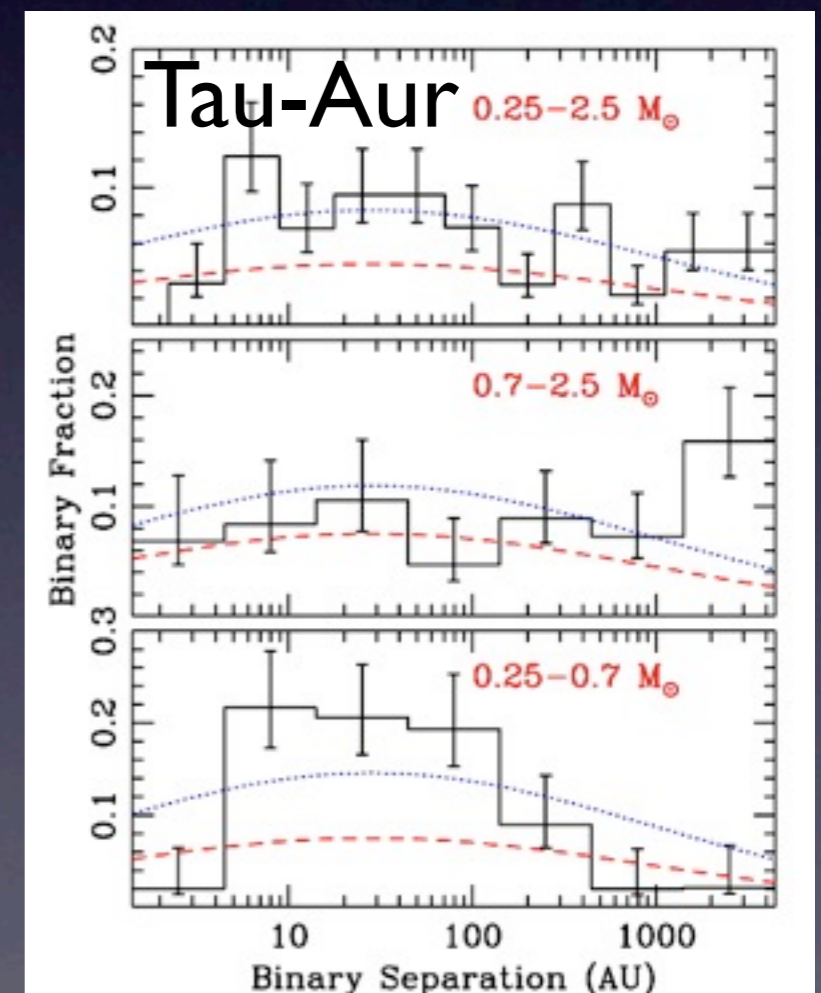

# T Tauri stars multiplicity

- Clear trends as a function of stellar mass

*Lafrenière et al. (2008)*

*Kraus et al. (2011)*

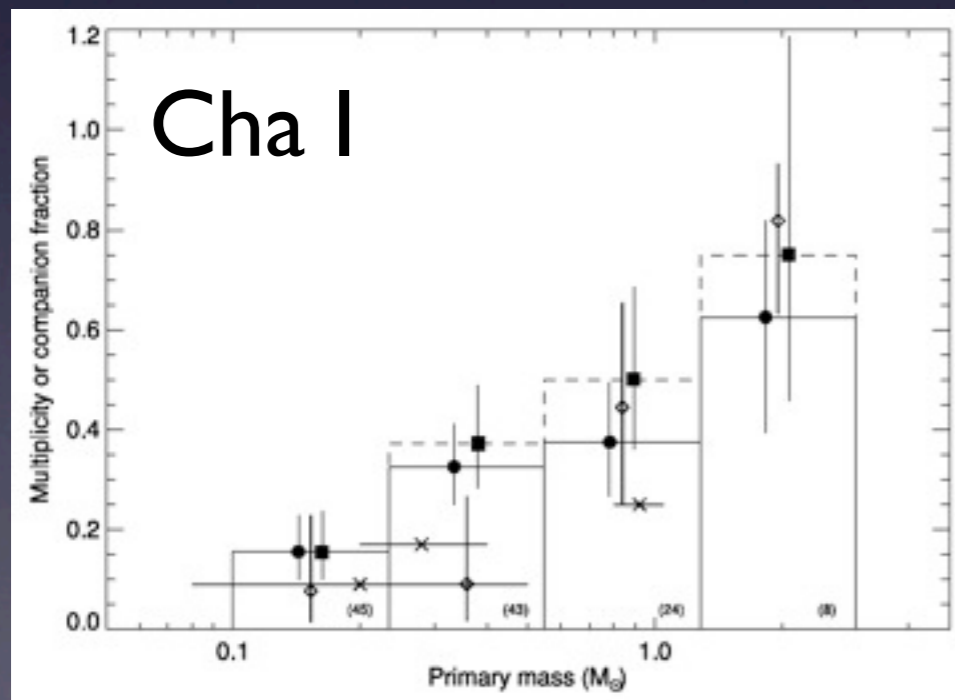

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# T Tauri stars multiplicity

- Clear trends as a function of stellar mass
  - ▶ similar to the MS trends
  - ▶ dynamics not important? too late?

*Lafrenière et al. (2008)*

*Kraus et al. (2011)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# T Tauri stars multiplicity

- Clear trends as a function of stellar mass
  - ▶ similar to the MS trends
  - ▶ dynamics not important? too late?
  - ▶ some wide BD-BD pairs
    - (see A. Kraus' talk)

*Luhman et al. (2009)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# Class I protobinaries

- Fairly large samples now known, allowing statistical multiplicity studies (down to 15 AU)
- High multiplicity, comparable to T Tauri stars in Tau-Aur and other associations

*Connelley et al. (2008)*

*Duchêne et al. (2007)*

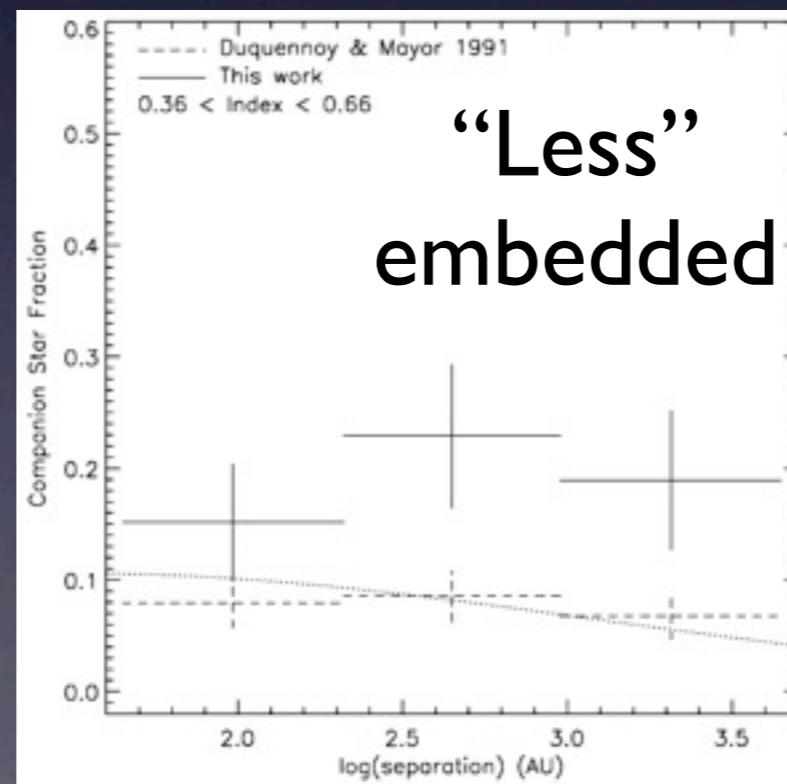

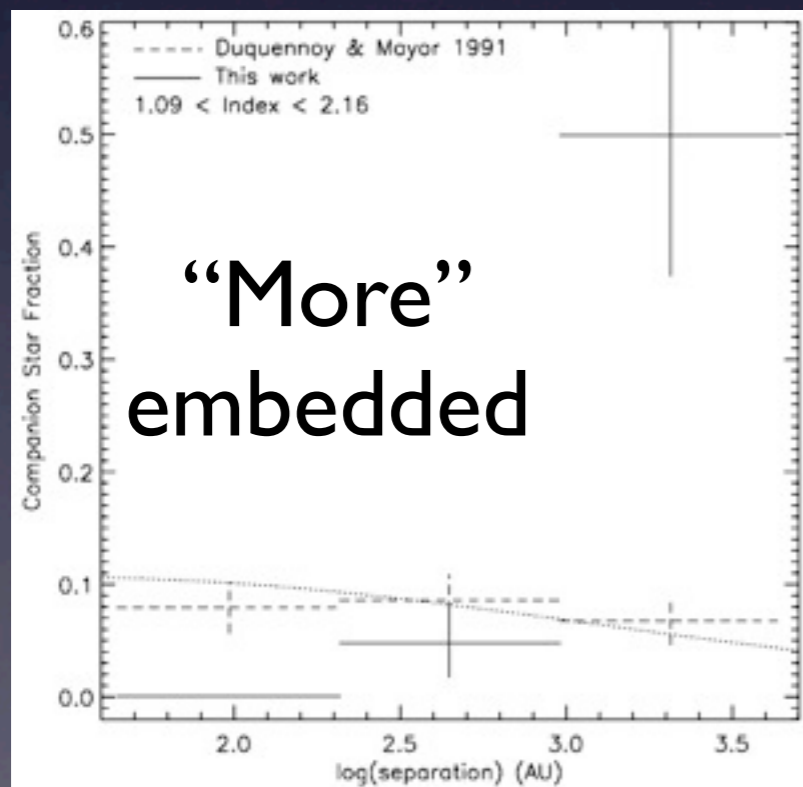

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# Class I protobinaries

- Tentative evolutionary trend
  - ▶ more embedded systems are much wider
  - ▶ “small groups” instead of binaries? or real?

*Connelley et al. (2008)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# Class I protobinaries

- Tentative evolutionary trend
  - ▶ more embedded systems are much wider
  - ▶ “small groups” instead of binaries?
- Tentative trend with environment
  - ▶ Orion (not ONC!) Class I binaries are predominantly tight, with separation close to/under 100 AU
    - *Duchêne et al. (2007), Connelley et al. (2008)*

# Class I protobinaries

- Tentative evolutionary trend
  - ▶ more embedded systems are much wider
  - ▶ “small groups” instead of binaries?
- Tentative trend with environment
  - ▶ Orion (not ONC!) Class I binaries are predominantly tight, with separation close to/under 100 AU
- Mass ratios cannot be reliably estimated!

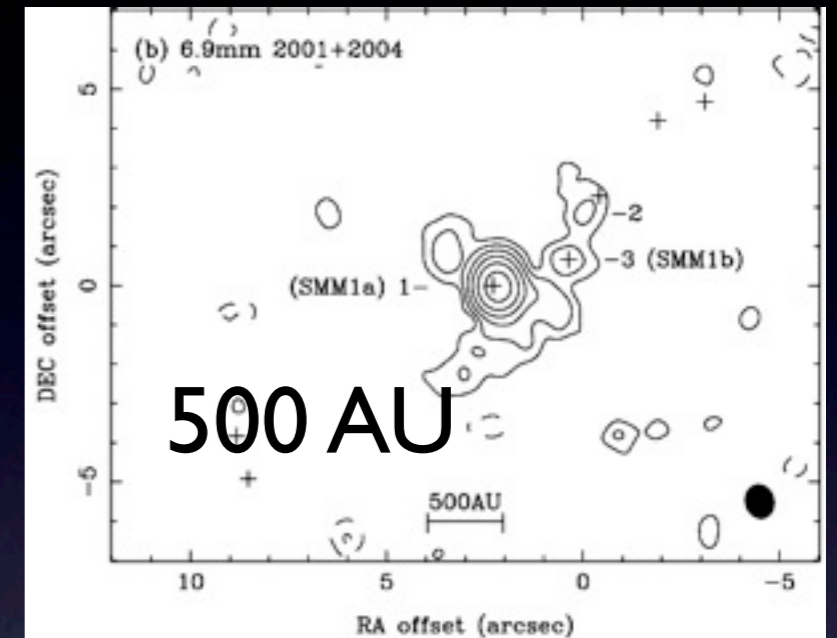

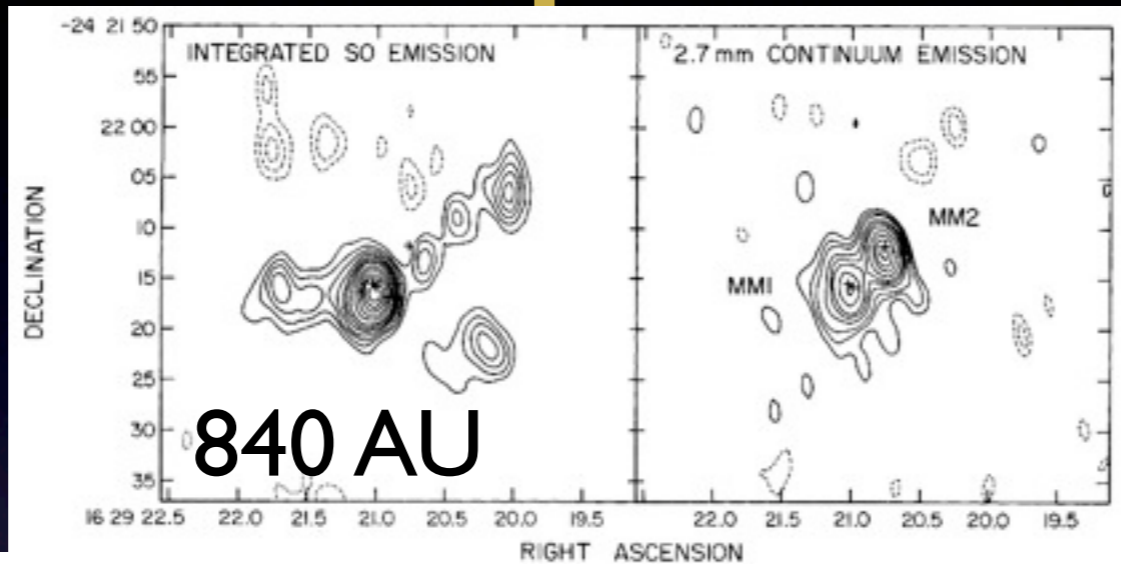

# Class 0 protobinaries

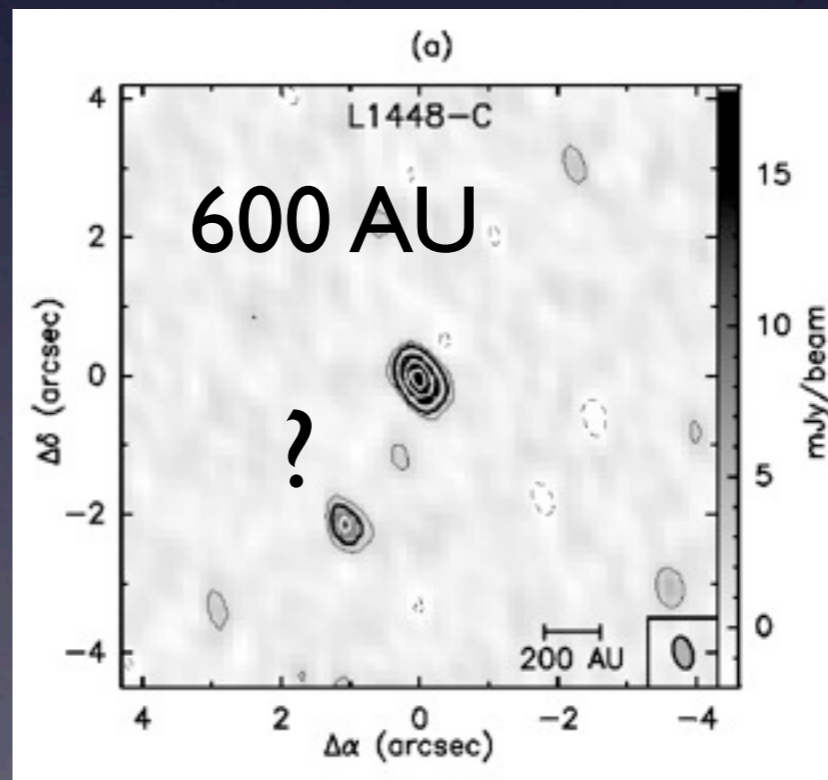

- This is the new frontier, as close to the “initial conditions of multiplicity” as can be
- Difficult observationally as massive envelopes get in the way (need interferometry)
- Large distances limit linear resolution
- Envelope/disk mass estimates, how does that translate to final mass ratio?

# Class 0 protobinaries

Mundy et al. (1992)

Enoch et al. (2011)

Choi (2010)

Maury et al. (2010)

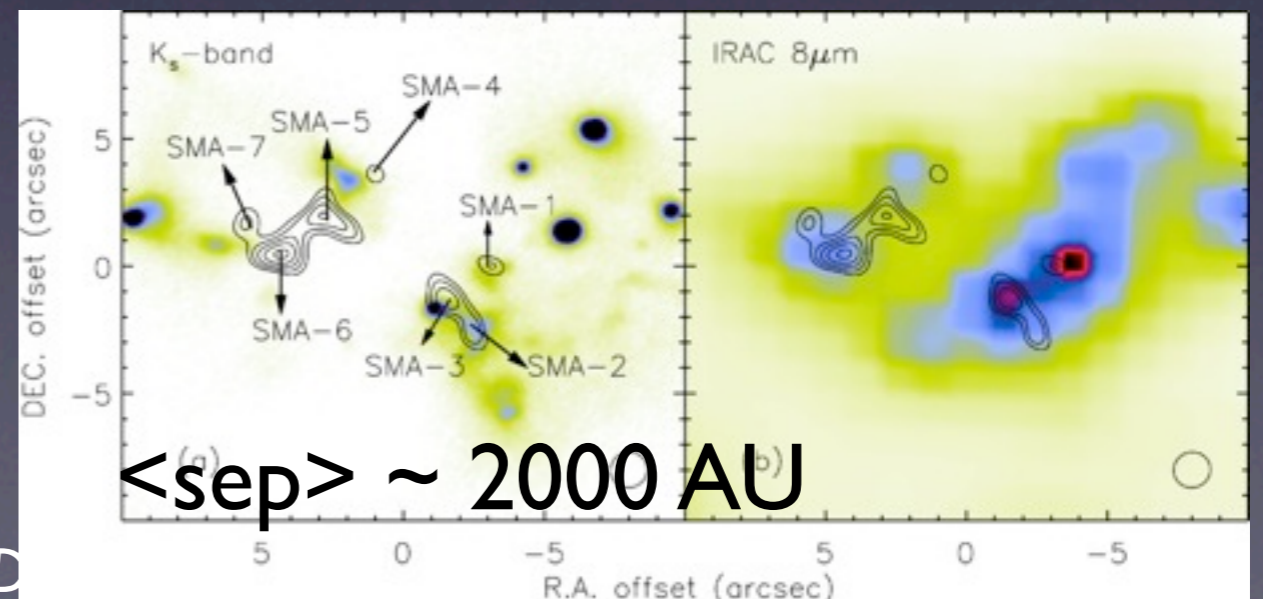

The formation of VLMSs and BDs - Garching - Oct 12 2011

# Class 0 protobinaries

- Low frequency at separation 100-2000 AU
  - ▶ ~10% instead of 20-30% in TTS and Class I sources
  - ▶ further orbital evolution? too early for fragmentation?
- Some systems in the 1000s of AU, but are these physically bound or “small groups”?

*Teixiera et al. (2007)*

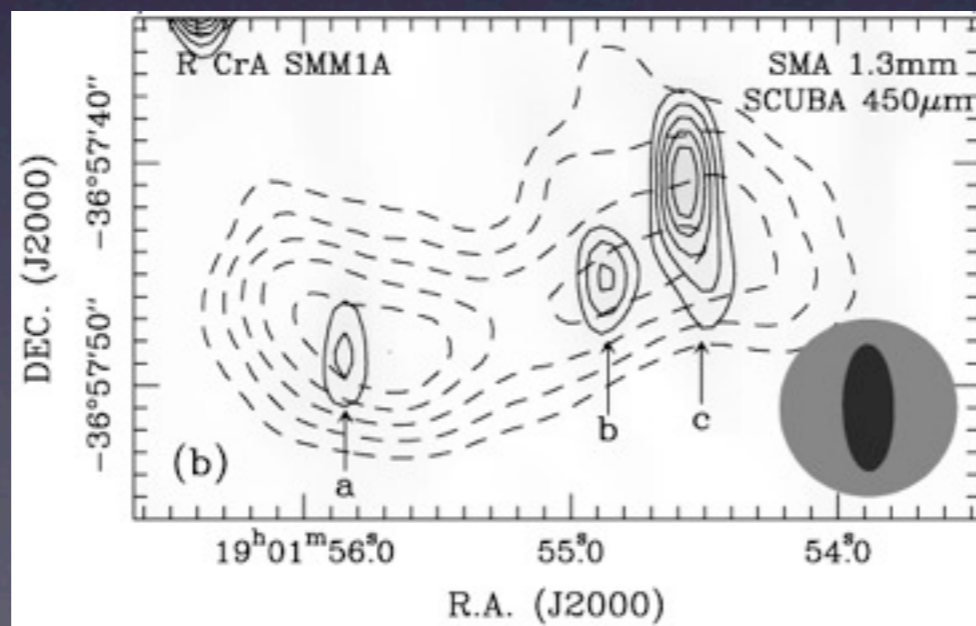

*The formation of VLMSs and BD*

# Core fragmentation?

- Going one step further back in time?
- Even more challenging observationally...
  - ▶ One example, but will it form a bound system?
  - ▶ only 10% of the total mass is in the fragments

*Chen et al. (2010)*

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# VeLLOs

- These are possible precursors to VLMS and BDs (although status still under debate)
- Too few candidates to reach any significant conclusion regarding their multiplicity properties
  - ▶ at least one wide binary (see T. Huard's talk)
- Will need reinvestigating in the future...

*The formation of VLMSs and BDs - Garching - Oct 12 2011*

# On the degree of multiplicity

- Single stars ( $N=1$ ) are the minority in the PMS phase ( $\sim 25-30\%$ ), except in clusters (?)
  - ▶ Not too many systems can be disrupted later
- High-order systems ( $N>2$ ) are relatively common among PMS populations
  - ▶  $\sim 1$  in 3 “binary” is a multiple
  - ▶ important for subsequent dynamical evolution

# Spectroscopic binaries

- Tight systems ( $<10-100$  AU) form through later fragmentation (in a disk?)
  - ▶ important role played by outer companions to exchange angular momentum
- They already exist by the T Tauri phase
- Relative lack of knowledge in the early phases, unfortunately (see P. Almeida's talk)

# Is multiplicity universal?

- Difficult to test really different environments because of (selection and observational) biases
- Protobinaries are not yet conclusive (lack of proto-clusters studied)
- Deficit of wide ( $> 1000$  AU) T Tauri binaries in clusters presumably is intrinsic (space density)
  - ▶ Is this related to the lower multiplicity at  $< 500$  AU ?

# Summary

- The multiplicity properties of the PMS populations can inform us on the physics of core fragmentation *and* later evolution
- Class I and Class 0 protobinary populations are now being established statistically
- Still only a partial picture, especially in the earliest phases (wait for ALMA!)
- VLMS/BD regime unexplored in Class 0/I

*The formation of VLMSs and BDs - Garching - Oct 12 2011*
