'ESO obs planning of future GW events', Jan 31/Feb 1, 2018

Outline

Gamma Ray Telescopes for GW Transients

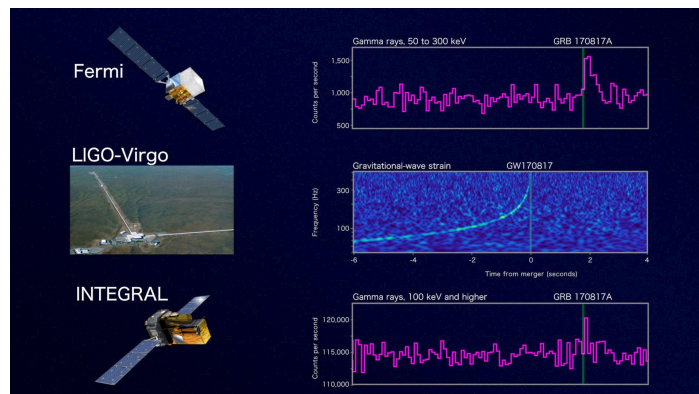

- ★ Fermi-GBM
- ★ INTEGRAL

Challenges in Data Analysis

- ★ Backgrounds
- ★ Responses
- ★ Analysis Approaches/Alternatives

Characteristics of Observations and of Constraints from Gamma-Rays

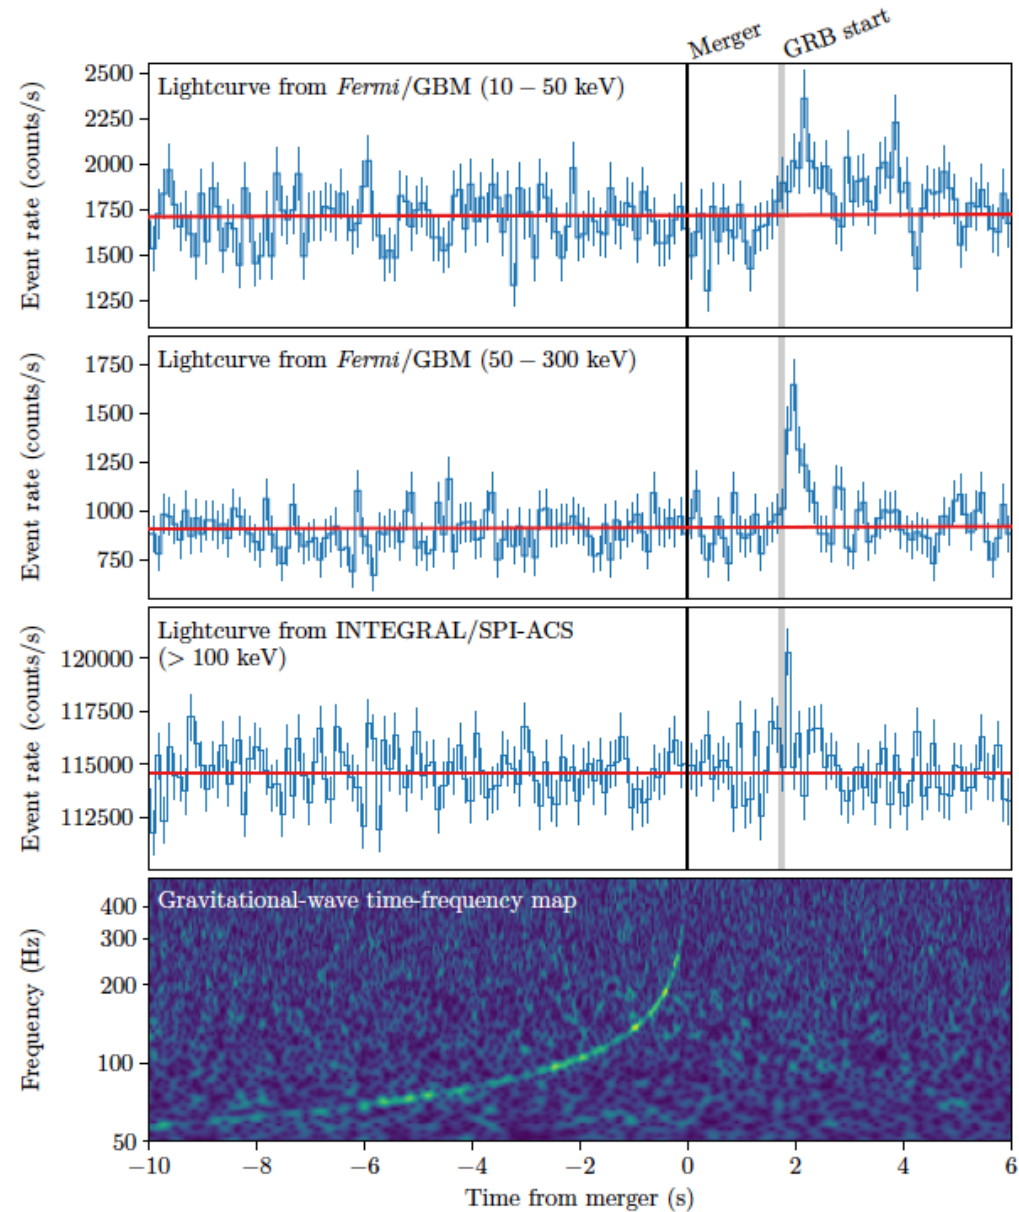

- ★ Transient Detection
- ★ Intensity Constraints
- ★ Timing Constraints
- ★ Spectral Constraints

GW170817/GRB170817A

gamma rays

and
gravitational waves

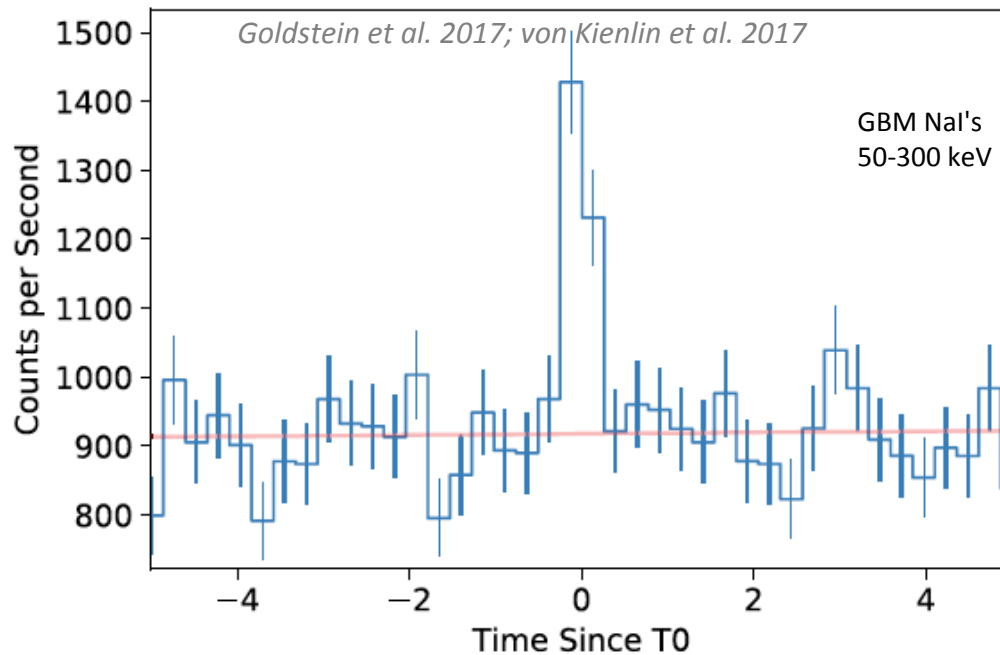

Fermi-GBM γ -ray measurements of GRB 170817A

GRB 170817A: a \sim normal/common short GRB trigger

(a)

(b)

- Duration rather long
- Spectrum on the soft side

INTEGRAL γ -ray measurements of GRB 170817A

GRB 170817A also seen with SPI/ACS!

Savchenko et al. 2017

- timing with **50 ms** precision
- spectral shape consistent with GBM's suggested one

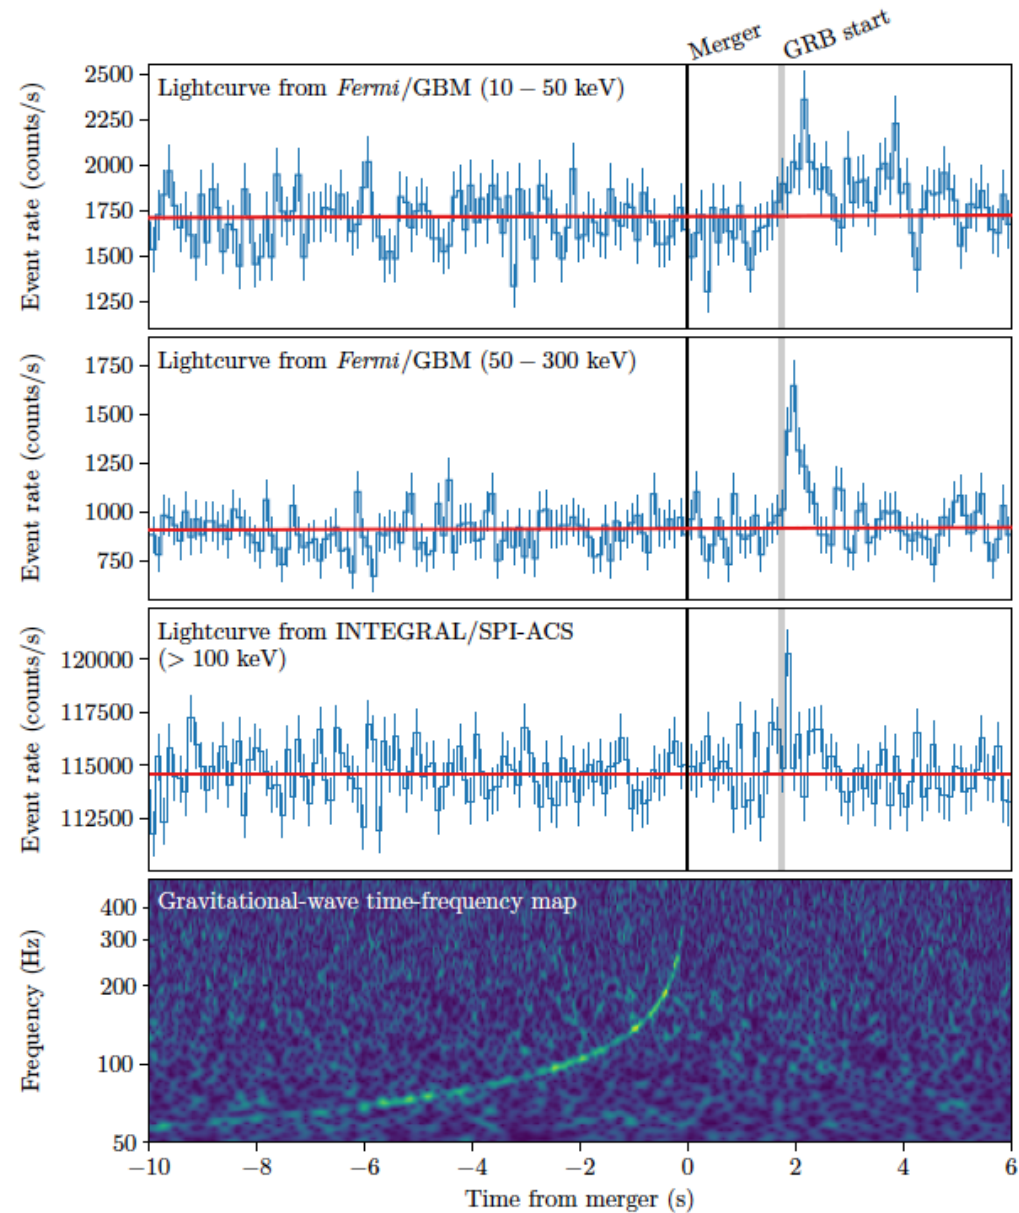

GW170817/GRB170817A

~coincidence

$\Delta \sim 1.88$ sec

sGRBs=NSMs(?)

The Gamma-Ray Burst Monitor (GBM) on the FERMI Mission

Germany (MPE, Jena-Optronik) and U.S. (NASA/MSFC)

12 Sodium Iodide NaI(TL) scintillation detectors

- ☆ Wide Field of View
- ☆ Burst Trigger
- ☆ Cover typical GRB spectrum: 8 – 1000 keV

2 Bismuth Germanate (BGO) scintillation detectors

- ☆ Energy range: 150 keV-40 MeV
- ☆ Spectral overlap with NaI and LAT

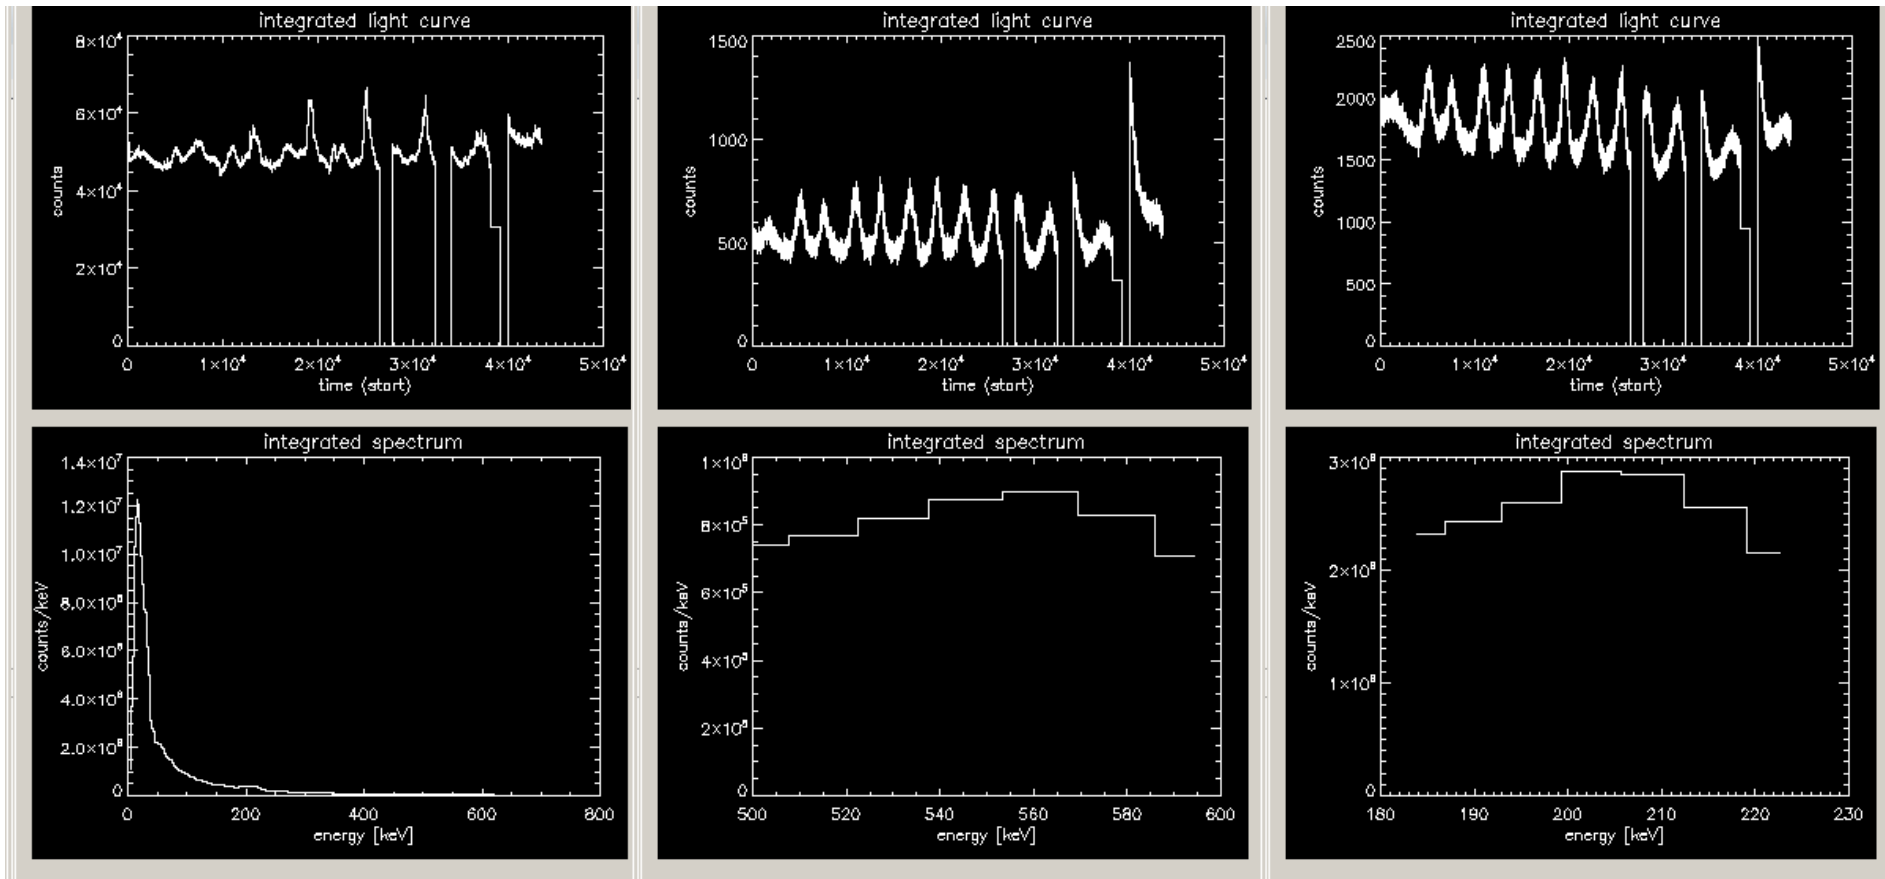

1 Power Box (PB)

1 Digital Processing Unit (DPU)

typically dominated by background from cosmic-ray activations

👉 one day of data:

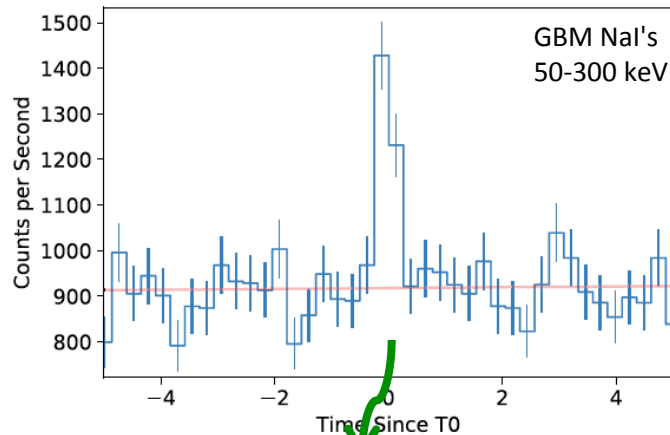

Fermi-GBM γ -ray measurements of GRB 170817A

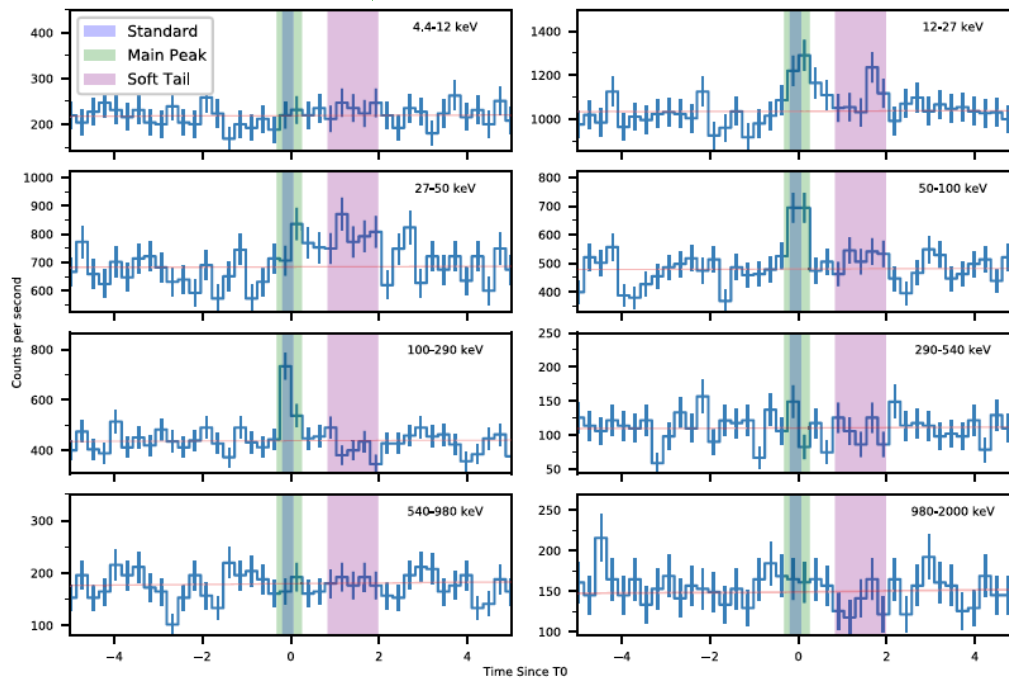

GRB 170817A: a \sim normal/common short GRB trigger

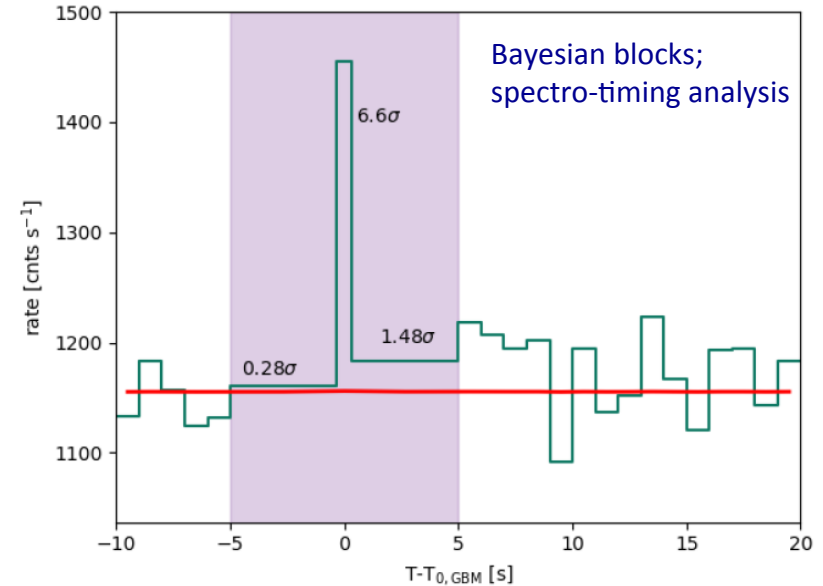

Goldstein et al. 2017

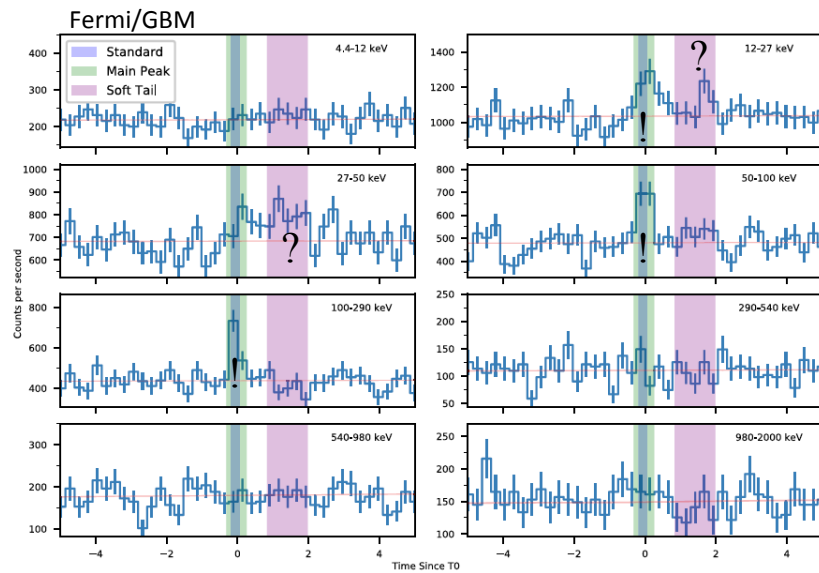

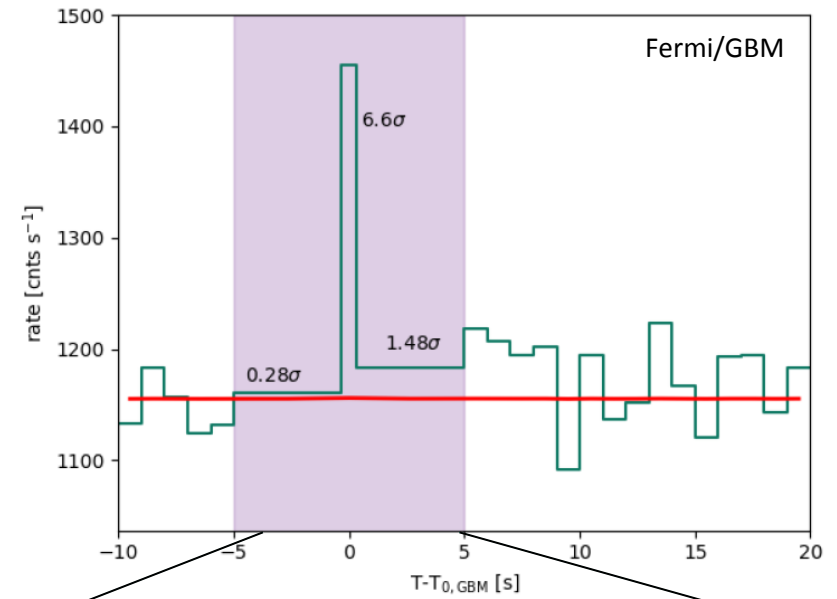

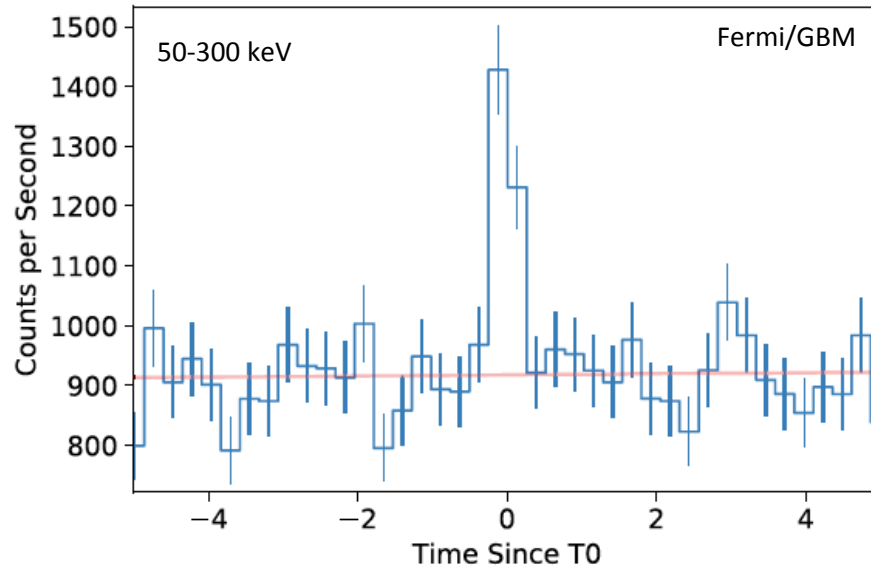

- Duration rather long
- Spectrum very soft
- a "soft tail?"

Burgess et al. 2017

Timing GRB 170817A

Limitations from spectral resolution of scintillation detectors $\sim 10\%$

- ★ Background dominates total countrates (\rightarrow no 'subtraction' allowed)
- ★ Spectral response and background systematics impose limitations

Fermi-GBM γ -ray measurements of GRB 170817A

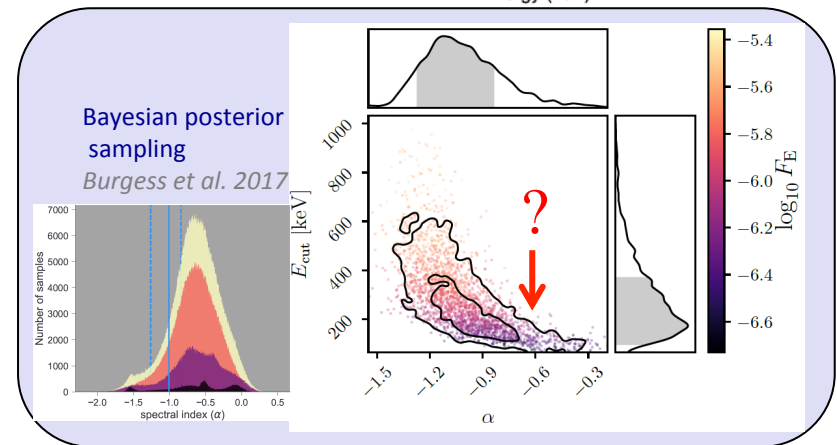

GRB 170817A: a \sim normal/common short GRB trigger

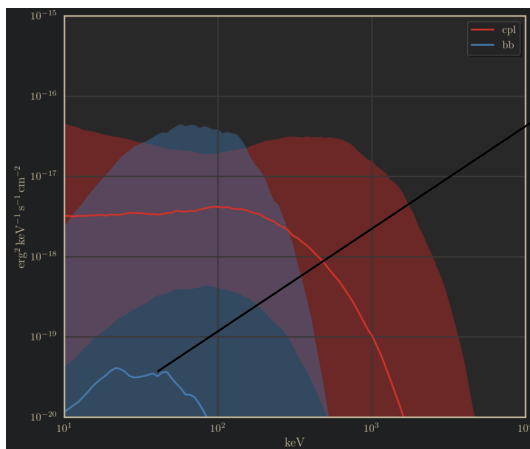

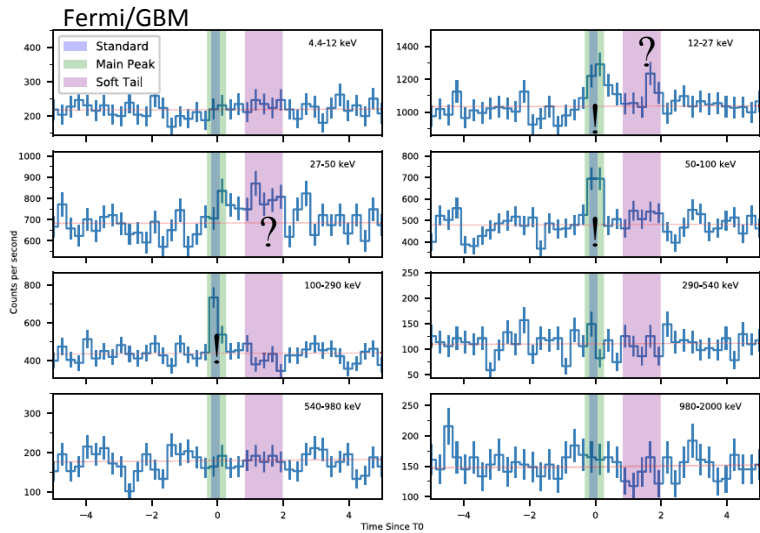

Goldstein et al. 2017

- Duration rather long
- Spectrum very soft
- a "soft tail?"

Spectral Constraints: GW170817/GRB170817A

Spectrum poorly constrained

★ Clear emission at ~100 keV only → "soft"

INTEGRAL Observatory (2002-...(2029))

★ Comptonised

★ Band fct

Response of GBM Detectors

- Effective sensitivity versus incidence angle:
 - ★ NaI's (~slice of scintillator) directional, especially at low energy
 - ★ BGO 'blocks': all-sky

Fig. 26 Off-axis effective area as a function of the irradiation angle (from -90° to 270°) for NaI FM 04 (*left panel*) and BGO EQM (*right panel*). In the case of NaI, results for three radioactive lines are shown, namely: Different curves represent different NaI line-energies: 32.06 keV from ^{137}Cs (*top green curve*), 279.2 keV from ^{203}Hg (*middle red curve*), and 661.66 keV from ^{137}Cs (*bottom yellow curve*). For BGO, two lines from ^{88}Y are shown: 898.04 keV (*blue curve*) and 1836.06 keV (*red curve*).

Exploiting Count Rate Differences Among Detectors:

(Connaughton+2015; Burgess+2018)

- Shadowing and aspect angle sensitivity provide individual detector responses for the 12 NaI's
- Earth albedo & scattering needs to be accounted for
- Monte-Carlo simulated responses have been assembled for ~100 sky directions
- a "best-fitting" direction thus can be evaluated
- Checking in hindsight (from afterglows, host galaxies), an offset of 8-13 degrees shows the limitations
- A finer (unbinned) sky direction treatment and inclusion of spectral properties in a Bayesian framework reduces systematics → locations within ~5 degrees achieved

cnts + spectral template

BALROG

Locating GRB 170817A

GRB 170817A, as compared to "typical short GRBs":

- duration rather long
- spectrum rather soft

$z=0.01$, while all other short GRBs $0.1 < z < 2$
 \rightarrow under-luminous by $10^4 \times$

- at least one other good candidate for nearby low-L GRB
- in total ~ 10 out of 50 short GRBs have similar spectral properties, and thus could be local and off-axis

Models for prompt gamma-ray emission

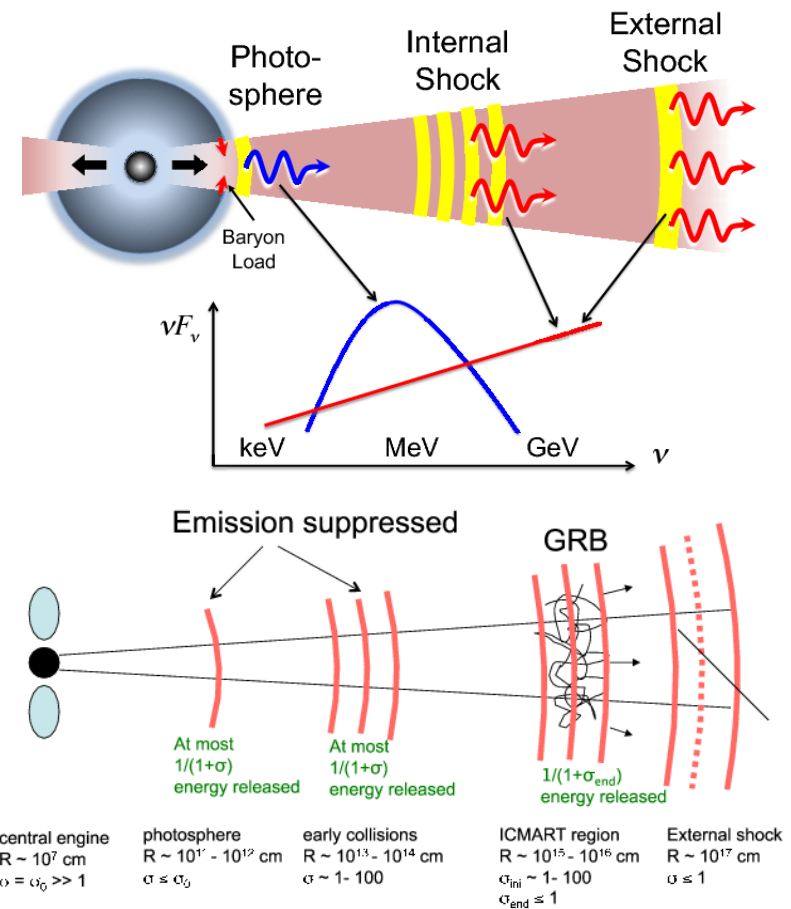

Standard model:

Synchrotron emission from the electrons that were Fermi-accelerated in these internal shocks

(but not undisputed: main problem is the necessary high efficiency)

Alternative models

- Photospheric emission: sub-photospheric heating leads to broadening of Planck spectrum
- Magnetically dominated jet: magnetic reconnection leads to broad-band spectrum

Post-merger dynamics

disruption of less-massive neutron star \rightarrow ejection, nuclear reactions

*Fernández & Metzger 2016
from Rezzolla+ 2011, and
Fouchart+ 2014*

Candidate r-process sources

neutron capture in an intense flash; seeds contain heavy elements

- ★ Need neutron-rich nuclear plasma (free nucleons)
- ★ Explosive environment
 - ☞ Supernova explosions; regions near proto-neutron star (ν -driven wind)
 - ☞ Neutron star's violent interactions (\rightarrow ejected material??)
- ★ Y_e (neutron richness of nucleon ensemble) is a key parameter
- ★ Nuclear fission (cycling) may regulate towards a homogeneous outcome

The scientific question "origin of the r process"

Standard arguments:

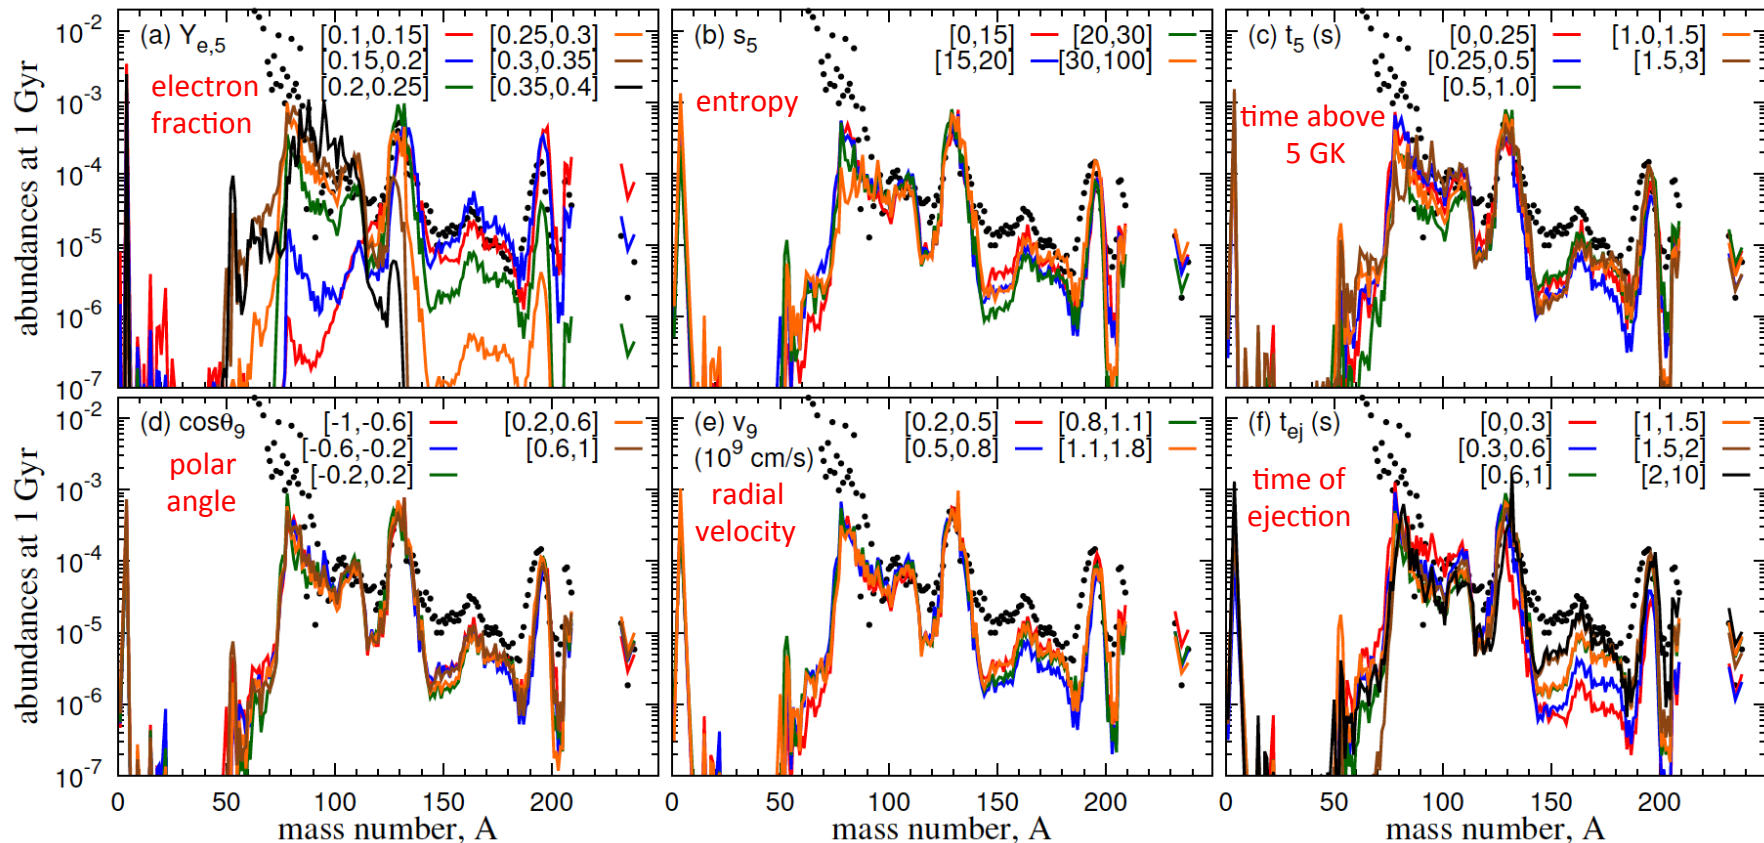

- Solar-system elemental abundances of heavy elements originate from the r-, s- and p- processes
- The s process is "known" and can be subtracted
- The remaining r process pattern is due to well-regulated astrophysical and nuclear processes → *the quest*

r process nuclear reaction dynamics

Nuclear processing of NS merger material

neutron capture in an r-process near colliding neutron stars

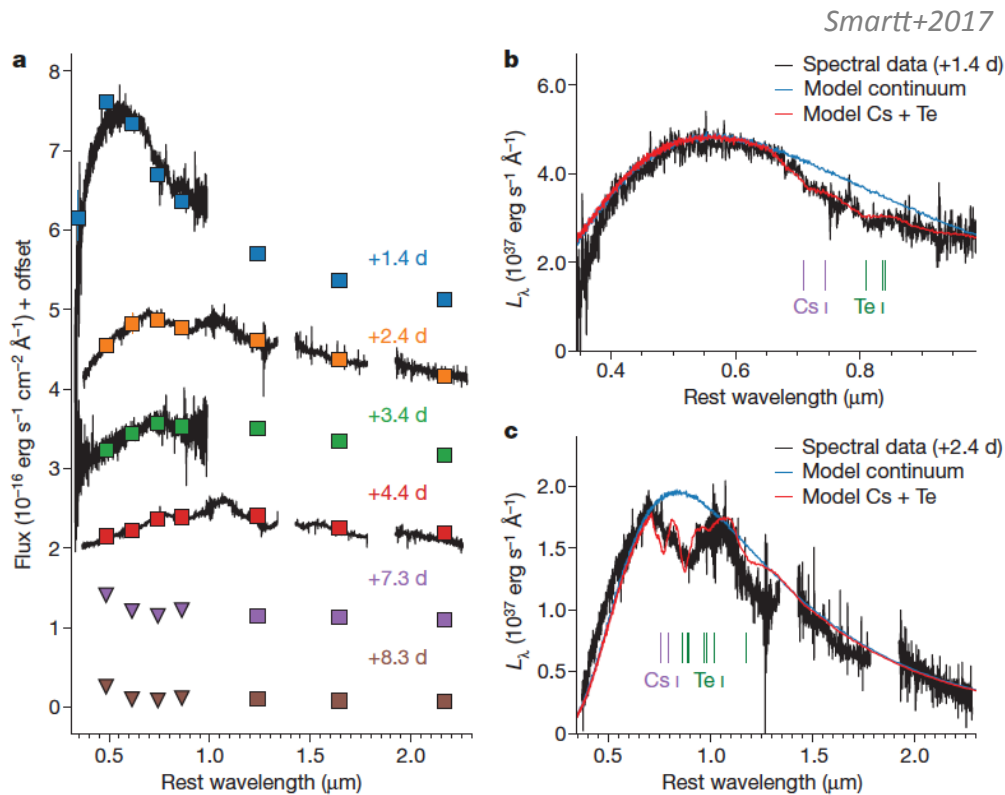

Electron fraction is most critical, otherwise well regulated

Wu, Fernández, Martínez-Pinedo, & Metzger 2015

Nucleosynthesis from a NSM

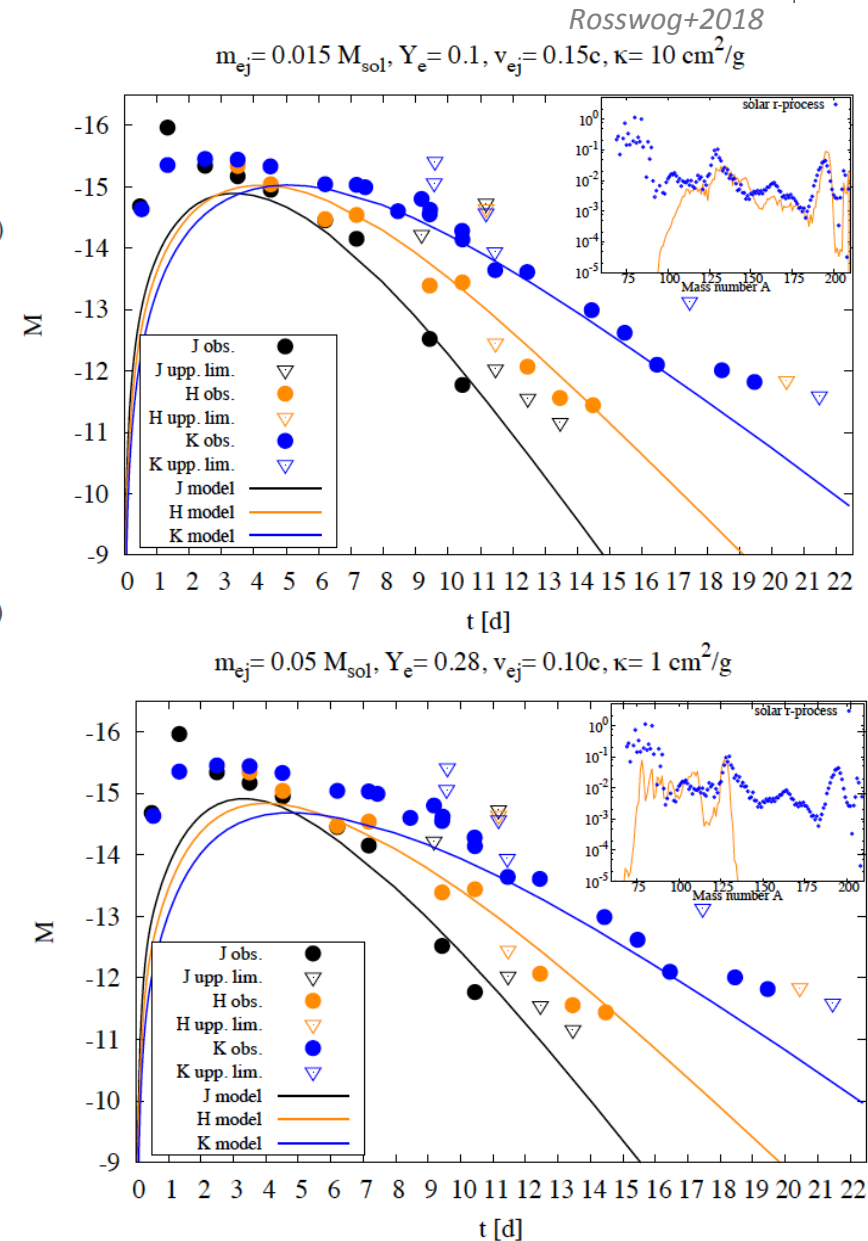

radioactivity from r-process isotopes !

★ which isotopes?

👉 heavy (up to $A \sim 195$) ??

👉 lighter ($A < 130$) ??

Emergent Radiation: Opacities

Figure 2. Graphical sketch of the three ejecta components radially expanding from the remnant. Different colors correspond to different matter opacity: high (red), intermediate (orange), low (blue).

Perego+2017

Nuclear-line astronomy

Nuclei (=isotopes!) reveal nucleosynthesis by their decays.

Indirectly, the radioactive decay produces hot envelopes, and radioactive afterglows.

Superposition of many radioactive species

...we know gamma-ray lines from radioactivity:

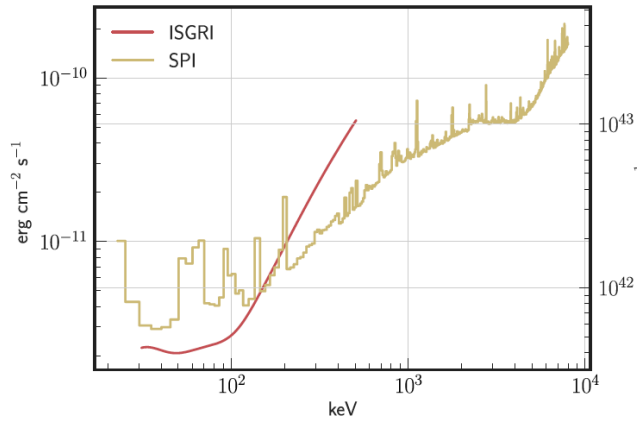

INTEGRAL γ -ray line measurements of GW170817?

GW170817 is too distant!

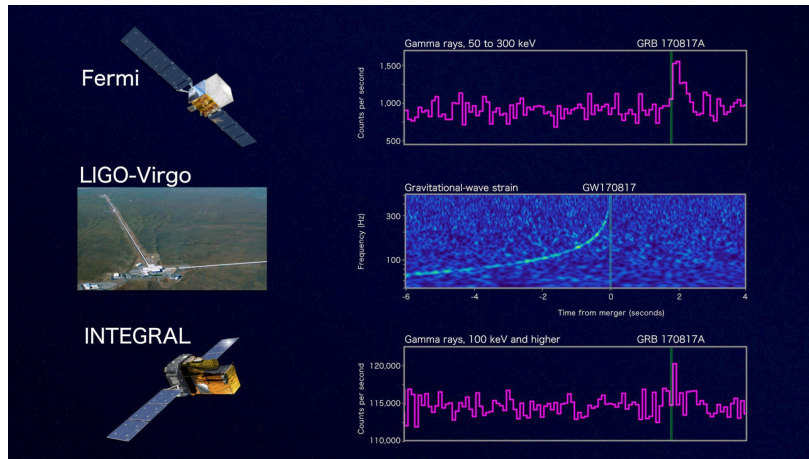

Savchenko et al. 2017

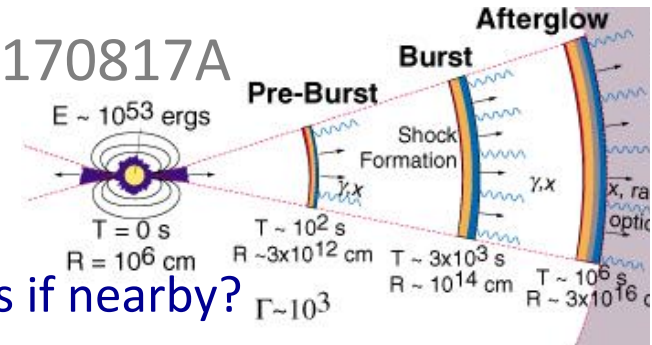

'ESO obs planning of future GW events', Jan 21/rev 1, 2016

Summary: Gamma-rays from GW170817

Gamma-ray signal seen from GW170817 as GRB170817A

- ★ clear detection of emission at ~ 100 keV – a short GRB
- ★ ~ 2 sec after GW chirp
- ★ surprisingly faint \rightarrow sGRBs different from expectations if nearby?

Radioactivity powers electromagnetic afterglow

- ★ nuclear burning \rightarrow heating of an envelope \rightarrow 'macronova'
- ★ probably related to r process (so: observationally-confirmed source)
 - \rightarrow we still do not know which objects contribute how much to trans-Fe element synthesis
- ★ too faint to use characteristic gamma-ray lines as unique diagnostic

Perspectives: New/better observations?

- Can do now >one o.o.m. better now
- ★ Compton Telescope most promising

But:
 Not before >10 years
 Not for narrow lines
 ...
 → Maintain INTEGRAL/SPI !!
